Opinions in regard to treatment vary very considerably, but from our very limited experience and study of the literature, the following would seem feasible: (1) Probangs, coin-catchers and all methods of blind bouginage should be abolished. (2) In all cases of *suspected* foreign bodies in the œsophagus, œsophagoscopy should be performed, even if X ray examination is negative. (3) Any case showing abnormality of the œsophageal mucosa should be kept under observation for a few days. No food should be given by mouth but administered per rectum. Repeated X ray examinations of such patients should be made. (4) Subcutaneous emphysema does not demand puncture unless there is evidence that it is followed by infection. (5) It is justifiable to attempt drainage of a para-œsophageal abscess due to an eroded perforation by endoscopic methods. (6) Known perforations with para-œsophageal emphysema but without general septic symptoms require no active treatment. They should be confined to bed and fluids should be given by the rectum ad lib. and nothing at all by mouth for three or four days. (7) Cases with known perforations and general septic signs must be treated surgically. They require gastrostomy, and if the perforation is: (*a*) Above the level of the fourth dorsal vertebra, the para-œsophageal space should be drained by a "cervical mediastinotomy" after the method of Furstenberg.[6] (*b*) Below the level of the fourth dorsal vertebra, a thoracic surgeon should be requested to drain through a posterior mediastinotomy.

Our thanks are due to Dr. Joseph Unsworth of St. Helens for his notes on Case 1 after her discharge from hospital.

CHRONIC CONSTRICTIVE PERICARDITIS

(PICK'S DISEASE)

TREATED BY PERICARDIAL RESECTION*

BY PAUL D. WHITE, M.D. Harvard

FROM THE MASSACHUSETTS GENERAL HOSPITAL, BOSTON, MASS.

(*Concluded from p. 548*)

Groups A (cured cases), B (greatly relieved), C (dying primarily from the lesion itself) have now been detailed. There remain for consideration Group D (the cases who died of complications) and Group E (the living patients, in whom the diagnosis was made on clinical grounds and X ray evidence, but not proved by operation).

Group D.—CASES WHO DIED OF COMPLICATIONS

Case 11 died of otitis media, bilateral empyema, and acute pancreatitis a few days after pericardial resection, Case 12 died of chronic *Staphylococcus aureus* infection involving a pericardial sinus and lung abscesses one year after operation, and Case 13 died a few days post-operatively probably of true portal cirrhosis and the effect of posterior pericardial adhesions.

CASE 11.—L. A., male, negro, aged 18, entered the medical service of the Massachusetts General Hospital in August, 1930, acutely ill with a large pericardial effusion and slight fever. The heart sounds were distant; there were no murmurs. There was a markedly "paradoxical" pulse, the cervical veins were distended, and the liver was enlarged. During the course of the next three months the pericardium was tapped ten times and much bloody fluid was removed. Oxygen was injected after four of the pericardial paracenteses in the course of two months in the hope of preventing chronic constrictive pericarditis. This object, however, was not achieved, as will be seen later.

The patient was discharged home on Feb. 7th, 1931, much improved, and he resumed light activity. Shortly, however, swelling of the abdomen and dyspnœa on effort developed and he returned to the hospital. There, on April 16th, 1931, partial pericardial resection was performed by Dr. Whittemore; the patient was slightly but not satisfactorily improved. The microscopic section of the thickened pericardium which was removed showed the presence of tuberculosis. The patient was discharged with draining pericardial sinus to a tuberculosis sanatorium on June 26th, 1931.

---

* The St. Cyres Lecture of the National Hospital for Diseases of the Heart, London, July 10th, 1935.

After 11 months in the sanatorium and another few months of convalescence at home and in California he improved a good deal, but soon after this he began to notice the recurrence of dropsy.

He re-entered the hospital on Feb. 5th, 1934, and showed a completely healed anterior thoracic scar, a somewhat enlarged heart with good sounds and no murmurs, neck veins slightly distended, a "paradoxical" pulse, and a blood pressure of 108 mm. systolic and 80 diastolic. There were enlargement of the liver (edge felt four fingers-breadth below the costal border), slight ascites, and moderate œdema of the legs. His serum protein was 4·1 per cent.

The X ray examination showed some increase in the heart shadow and in the supracardiac shadow. There was evidence of partial fixation of the heart, more marked on the right than on the left.

The electrocardiogram showed normal rhythm, rate 70, with low voltage, and low T waves in all leads.

The urine was negative, and blood examination showed leukocytosis 12,000 to 18,000 with no anæmia. The Hinton reaction was negative.

Further surgery seemed indicated, and on Feb. 23rd, 1934, a long incision was made mediate to the old incision extending out toward the axillæ. The sternal muscle flap was turned up and some sternum removed, and also some cartilage of ribs. The pericardium was found very thick and adherent to the heart. Several large sections of the pericardium were freed from the heart and excised, more on the left than on the right. The pericardium which was removed showed fibrosis.

Two weeks after the operation the patient seemed definitely improved. The abdomen was smaller. He had less dependent œdema, and he felt more comfortable. There had been slight spontaneous diuresis for ten days beginning the third day after operation. There was a loss of 5½ lb. in weight as a result of the diuresis. The day after discharge from the hospital he developed a left earache, followed by fever and chills. An acute otitis media had to be treated by incision. Following this there were severe pain in the left flank, nausea, and vomiting, and he was readmitted to the Massachusetts General Hospital very ill on March 16th. He died on March 22nd, 1934, and post-mortem examination showed a bilateral empyema with acute pancreatitis, subsiding left otitis media, chronic tuberculous adhesive pericarditis, cardiac cirrhosis of the liver, ascites, and peripheral œdema.

CASE 12.—Miss H. E. P., female, aged 31 at the time of her admission to the Massachusetts General Hospital, August 5th, 1930. Her past and family histories were of no importance. In 1928, two years before admission, she had an abscess in the right ear followed by severe earache and mastoid pain. There was a discharge for several months from that ear. Soon after the onset of this ear trouble she noticed dyspnœa on exertion, palpitation, and œdema of the ankles at night. For the ear condition she entered the Eye and Ear Infirmary twice, the second time in February, 1930, at which time anæmia was found and treated. Her tonsils were removed in June, 1930. On getting up from bed after this operation she noted an increase in dyspnœa and œdema with some swelling of the abdomen. She was put back to bed, given digitalis, and also treated for a moderate secondary anæmia.

She improved at first but then her symptoms recurred and she entered the Massachusetts General Hospital on April 10th, 1931. Examination showed some cyanosis, increased jugular venous pulsation, no increase in cardiac area to percussion, fair heart sounds with third sound at the apex, dullness at the right lung base, enlarged liver as before, and atrophy of the arms and legs. There was little evidence of ascites. The blood pressure was 120 mm. systolic and 80 diastolic. The pulse was regular at about 90. There was very slight fever, at times up to 99 and 100° F. The blood showed as before secondary anæmia but less severe. There was an occasional leukocytosis. The urine was not remarkable. By chest tap clear straw-coloured fluid was obtained with a specific gravity of 1·018. This fluid was negative for tuberculosis on guinea-pig inoculation. X ray showed slight increase in the width of the heart shadow and calcification of the pericardium forming a definite ring from the region of the pulmonary conus down to the diaphragm. The left auricle appeared to be enlarged. The interlobar septum was visible on the right. There was evidence of a small amount of fluid at the right base.

The electrocardiogram showed auricular premature beats interrupting normal rhythm at a heart-rate of 100 with low voltage and low T waves.

The venous blood pressure was 15 cm.

On April 29th, 1931, she was transferred to the surgical service for decortication of the heart by pericardial resection by Dr. Whittemore. Parts of the fourth, fifth, sixth, and seventh costal cartilages and the edge of the left border of the sternum in this region were removed. The pericardium was opened through a calcified area. In one place there was a small collection of thick, white pus. Culture of the pericardial pus showed no growth and no organisms were seen in the smear. With considerable difficulty a line of cleavage was made between heart and pericardium, and a considerable portion of the anterior pericardium was removed with rongeurs. The apex was free. There was considerable bleeding from the removal of the calcified pericardium in the region of the diaphragm. This was controlled with a gauze pack. The pericardium which was removed showed fibrosis and numerous large foci of calcification. There was no evidence of tuberculosis.

Following the operation the patient seemed more comfortable, and was able to move about more freely. Because of the finding of pus at the time of operation a wick was left in the operative wound, and the sinus continued to drain freely. She showed occasionally a slight fever, but no leukocytosis. She was discharged to a convalescent home on June 11th, 1931. She was readmitted to the hospital on June 28th, 1931, because of chills and fever, pain in the lower left chest, and persistence of the post-operative pericardial sinus. Her general condition was much the same as before. Culture of the pus from the sinus was positive for *Staphylococcus aureus*. The smear showed gram-positive cocci, but no tubercle bacilli. The sinus was discharging thick green pus. During the next few months her condition remained essentially unchanged, but gradually through the winter she grew weaker, with increasing symptoms of pulmonary trouble, and died on April 18th, 1932.

Autopsy showed fibrous pleural adhesions in both chests with two abscess cavities in the right lung, thick calcified pericardium extending in places into the myocardium, and a draining pericardial sinus. The heart was slightly enlarged without dilatation. The mitral ring showed slight calcification. The tricuspid orifice was almost occluded by a ball thrombus, attached by a small pedicle to the wall of the right auricle.

CASE 13.—J. A. H., male, 52, a shoe worker, began to notice shortness of breath on effort in January, 1932. In July, 1932, swelling of the ankles began. In September his œdema had reached the thighs, and he was hospitalised for five weeks. At Christmas time he had the grippe. Pleural effusion developed and in February each pleural cavity was tapped with the removal of much straw-coloured fluid. He showed some asthmatic wheezing after each tap. Chest taps were continued from April, 1933, at the rate of about one a week until his entrance to the Massachusetts General Hospital on Sept. 23rd, 1933. He lost strength steadily over this period of time, but the œdema of his legs subsided somewhat. His past history was entirely unimportant. He had tonsillectomy eight years before, after tonsillitis. Family history was unimportant. Physical examination on admission to the Massachusetts General Hospital on Sept. 22nd, 1933, showed a well-developed and nourished man, slightly dyspnœic, but in no great discomfort. The cervical veins were engorged and pulsating, with his head and neck at an angle of 45°. The cardiac apex impulse was poorly felt. Percussion dullness was slightly increased. The heart rhythm was absolutely irregular, and the rate was 60. The blood pressure was 104 mm. systolic and 60 diastolic. There were a moderately loud blowing systolic murmur and a loud third sound at the apex. The pulmonary second sound was slightly accentuated and reduplicated. There were no diastolic murmurs. The pulses were small. There was dullness to flatness below the angle of the right scapula and at the extreme left base, with diminished breath sounds and slight pleural friction rub at the right base. There was slight œdema over the lower back and of both legs up into the thighs. There was moderate ascites. The liver edge was palpable, five fingers-breadth below the costal margin; it was not tender.

Fluid which was obtained from abdominal and pleural cavities was evidently a transudate. When inoculated into a guinea-pig, the abdominal fluid was negative for tuberculosis.

The urine showed slight albuminuria. The blood was normal except for slight secondary anæmia. The serum protein measured 5·3 per cent. The Wassermann reaction was negative

X ray examination showed extensive calcification of the pericardium, especially in a circular region from the pulmonary artery downward to the diaphragmatic surface of the heart and transversely to the midline. Pulsation of the heart was not evident except at the apex where it was quite distinct. There was considerable fluid in both pleural cavities.

The electrocardiogram showed auricular fibrillation with a ventricular rate varying from 60 to 110, and markedly low voltage with inverted T waves in Leads 1 and 2.

After observation in the ward over a period of ten days this patient was transferred for operation, and on Sept. 30th, 1933, Dr. Churchill performed pericardial resection. The pericardium was found greatly thickened and calcified, particularly over the right ventricle. The line of cleavage was established over the left ventricle, and the pericardium was freed around the apex at the left side of the heart. With considerable difficulty the calcified pericardium was removed from the right ventricle and the diaphragmatic pericardium was resected down to the vena cava. There was a stormy post-operative course with pulmonary œdema. Both pleural cavities were again tapped, the right on Oct. 3rd and the left on the 4th. He died suddenly on Oct. 5th.

Post-mortem examination showed chronic adhesive pericarditis with calcification, especially posteriorly, but without evidence of tuberculosis, acute and chronic bronchitis and slight broncho-pneumonia, pulmonary œdema, slight right hydrothorax, chronic fibrous bilateral pleuritis, marked cirrhosis of the (liver of the chronic portal type, not of the lesser degree associated ordinarily with cardiac cirrhosis), perisplenitis, cholelithiasis, ascites, and peripheral œdema.

Group E.—LIVING CASES NOT PROVED BY OPERATION

Two living cases were not proved by operation but by characteristic signs and X ray evidence of pericardial calcification.

Case 14.—W. J. B., a physician in general practice, aged 57 years, consulted me, Jan. 4th, 1930, with the following history.

He had had "dry pleurisy" in 1894 while studying medicine. Closely following this there was fever with enlargement of the liver and neck veins which persisted for several months that summer. The legs were also slightly swollen. He resumed his studies and improved slowly so that he lost his œdema, but his liver remained somewhat enlarged. From 1896 to 1916 he carried on a vigorous country practice with little limitation, but some dyspnœa on climbing stairs. In 1916 he had a respiratory infection followed by some congestion of his liver and legs. He improved, but again the next year, 1917, he had influenza, and after that serious congestion from which he gradually recovered in the course of a year. He resumed work in 1918. In 1922 he began to have paroxysms of very irregular tachycardia lasting several days and recurring every two or three months. He took some digitalis for this. The attacks decreased gradually in frequency so that in 1927 and 1928 he had only five or six paroxysms altogether. At Christmas time in 1928 he had another respiratory infection and this was followed by constant cardiac arrhythmia. In April, 1929, his wife died suddenly, and following this shock he was forced to go to bed, and had acute congestion lasting three months. With rest and digitalis he had slowly improved up to the time of his visit to me. On examination I found him well developed and nourished with the following abnormalities; slight to moderate fullness of the arm and neck veins, heart very slightly enlarged in size with a loud third sound at the apex (there were no murmurs), very irregular heart rhythm with a rate of 75, and the liver enlarged with a non-tender edge felt two fingers-breadth below the costal border. There was no evidence of ascites or œdema of the shins. The lungs were clear. The blood pressure was 115 systolic and 85 diastolic. The electrocardiogram showed auricular fibrillation with a ventricular rate of 70 to 80, and low T waves. Fluoroscopic examination showed the heart somewhat enlarged, and somewhat fixed, with areas of pericardial calcification, especially at the left upper and inferior borders of the heart.

Pericardial resection was not advised, because of his age and relatively slight incapacity. On Oct. 22nd, 1930, he was examined again and showed no changes. On June 8th, 1932, he wrote of his reasonably good health with the same signs as before. He was carrying on a light practice.

Case 15.—Mr. A. B., Jewish tailor, aged 45 years. He had always been well and active except that for a number of years he had noticed gradually increasing shortness of breath. In the summer of 1930 because of chronic constipation and heart-burn he went to a local hospital for study. There he was told that he had an abnormal heart condition. He returned home improved. In the fall of 1930 he had much increase in dyspnœa on exertion with a feeling of weakness, and stopped work. In the summer of 1931 he began to develop swelling of his ankles and abdomen and had some aching pain in his precordial region. He contracted a cold and sore-throat which caused him much discomfort and a troublesome cough. His physician told him that his heart was very bad, and gave him digitalis. In January, 1932, the swelling of his ankles increased and he had to sleep with his head high at night. His coughing was continuous. Early in February, 1932, he fainted and thereafter was sent to bed; shortly after this was referred to me for study and entered the Massachusetts General Hospital. The past history revealed no illnesses except for influenza in 1918 and 1920. The family history was not remarkable.

Physical examination showed a well-developed and nourished man, moderately dyspnœic, with slight cyanosis. His voice was hoarse. His tongue was slightly coated. His cervical veins were engorged. His tonsils were moderately enlarged. The heart was slightly enlarged. The sounds were fair, the pulmonary second sound accentuated. There were no murmurs. There was no Broadbent's sign. The heart rhythm was absolutely irregular. The pulse was small. The apex heart-rate was 130. The rate at the wrist was 100. The blood pressure was 115 mm. systolic and 90 diastolic. The lungs showed emphysematous breathing throughout with scattered coarse râles, and slight dullness at the right base. The abdomen was distended, the liver much enlarged. There was a considerable amount of ascites, but there was no œdema over the shins. Fluoroscopic examination showed moderate enlargement of the heart, especially at the left upper border with increase in the lung hilus shadows and pericardial calcification, easily seen about the apex in the right anterior oblique position. The electrocardiogram showed auricular fibrillation with a ventricular rate of 130 and diphasic S–T intervals in Leads 2 and 3. The voltage was rather low. The urine was normal. The blood was normal. The Hinton reaction was negative. The venous pressure was 21·5 cm.

He improved in the course of the next three weeks after digitalisation. His heart-rate dropped to 80. His liver decreased somewhat in size. The ascites and right hydrothorax disappeared. His neck veins remained only slightly engorged. His cyanosis was considerably less.

This improvement did not continue for long and in spite of constant digitalis therapy he was in a poor state of health when examined in September, 1934, with increasing dyspnœa, small pulse pressure (110 mm. systolic, 90 diastolic), big liver, and dropsy (slight ascites and slight œdema over the shins). Pericardial resection was considered but not done; he was by no means an ideal case for it.

Diagnosis

I shall now summarise our experience with these 15 cases of chronic constrictive pericarditis so far as it applies to the diagnosis of the condition. Twelve of the cases were proved by operation, one other by autopsy, and the remaining two by clinical evidence and X ray. Several other probable cases that I have seen I have not included.

Sex.—Nine of the 15 cases were males and 6 were females.

Age.—The ages of the individual cases at the onset of their trouble ranged from 5½ to 50 years, and at the time of operation from 11 to 52 years; at the time of the last follow-up note they were as follows: Well at 11, 14, 14, 21, 25, and 32 years. Much improved at 20. In mediocre health at 48 and 60. Dead at 22, 23, 32, 32, 36, and 52 years. Our oldest case successfully operated upon was in her thirty-first year.

Race.—Six of the 15 cases were of English stock, three French-Canadian, two Irish-American, one German-American, one Polish-American, one Jewish-American, and one Negro-American.

Cause.—The ætiology of the chronic pericardial disease can be assigned as follows: tuberculosis in two (questionable in two others), pneumonia with polyserositis (including both pleuritis and pericarditis) in two, sepsis in one, rheumatism in none, uncertain or unknown in ten (in five of which, however, there was a definite history of acute pericarditis). The absence of the rheumatic infection as an ætiological factor in our series is striking and is a distinct contradiction to frequent statements in the literature, even by present-day authorities, which are based as a rule on little or no personal experience or on cases not strictly belonging to this group, that is, on cases whose symptoms and signs are primarily due to valvular or myocardial disease or on cases in whom external pericardial adhesions are playing the preponderant rôle. It is of further interest that a series of 1000 children with the rheumatic infection studied at the House of the Good Samaritan in Boston, and followed over a period of ten years has shown in not a single instance any evidence of chronic constrictive pericarditis, even though the heart was often seriously involved in other respects and even though acute pericarditis had been noted in many cases during their acute rheumatic infection. Certainly, therefore, if rheumatism can cause Pick's disease it does so in only the rarest cases. As a matter of fact Chevers[9] had pointed this out in 1842.

Symptoms.—The first symptoms were dyspnœa in four cases, abdominal enlargement (that is, a big liver and ascites) in three, dyspnœa and abdominal enlargement in three, œdema of the feet and abdominal enlargement in two, œdema of the ankles in one, œdema of the face and abdominal enlargement in one, and soreness in the right upper quadrant in one. In all cases abdominal enlargement was present at some time during the illness; it was the only uniform symptom, but swelling of the feet and dyspnœa at some time or other also occurred in most of the cases. There was little pain or palpitation. Weakness was occasional. Some patients showed loss of weight in the upper part of the body. There was no fever except in two patients with subacute tuberculous infections and in several cases during intercurrent acute infections. In several cases it was clear that the symptoms of acute pericardial involvement passed over into those of chronic constrictive pericarditis.

Signs.—Two signs were consistently present in all cases: (1) *enlargement of the liver*—non-tender and non-pulsating—usually *with much ascites*, and (2) *engorgement of the jugular veins* with or without evident pulsation. The venous pressure when measured before operation was usually between 20 and 30 cm., three times or more the normal.

The reason for the preponderance of liver enlargement and ascites in the dropsy of the majority of cases of chronic constrictive pericarditis is probably to be found in the greater obstruction of the flow in these cases from the hepatic veins at or near their outlet into the inferior vena cava than of the flow in the vena cava itself. Such obstruction may be due to the pressure of locally constricting adhesions, or of fluid (as in acute pericardial effusion), or to anatomical variations in the venous relationships. Much further study of this problem is needed. It is to be noted in this connexion that dependent or generalised œdema antedated or overshadowed the liver enlargement and ascites in a few of our cases.

The *size of the heart* was normal in seven cases, slightly enlarged in five, and moderately enlarged in three. In at least some of the cases with apparent slight enlargement the thickness of the fibrosed pericardium itself could account for the increased measurements by X ray or physical examination. There were no *heart murmurs* in 12 cases; systolic murmurs, slight to moderate, were heard at the apex in the other three. There were no diastolic murmurs. The heart rhythm was normal in 11 cases, except for some extrasystoles in one; in the remaining four cases there was auricular fibrillation.

The *blood pressure* and *pulse pressure* were low in 11 of the 15 cases and low normal in the other four. In seven cases a well-marked "*paradoxical*" *or Griesinger-Kussmaul pulse* was noted, in two cases it was said not to be present, and in the remaining six cases it was apparently not looked for.

Broadbent's sign[6] was noted in no case, nor was inspiratory collapse of the neck veins; Friedreich[17] in 1864 had called attention to the presence of this latter sign in two cases of adhesive pericarditis, but it is important to note, as he himself stated, that the cause of this sign is in the action of external adhesions, and *not* from the effect of a constricting pericardium. There was *effusion into the pleural cavities*, in the nature of a transudate, in seven of the cases, generally in the sicker patients, and in one other case there was a terminal empyema.

Œdema of the legs was present in 10 of the 15 patients, being marked in four. The abdominal and thoracic walls were œdematous in seven patients and the face was swollen in two.

In no case was the spleen felt definitely.

X ray.—The heart shadow was normal in size by X ray in seven of the cases and slightly to moderately enlarged in the remainder. The shape varied greatly from normal to so-called mitral with prominence of the left upper border, and in three cases there was indication of left auricular enlargement (two of these patients had auricular fibrillation). The amount of pulsation present varied widely from fairly free on both sides to little or none anywhere. It was quite a common finding to observe free pulsation at the cardiac apex and left border with no pulsation at the right border (which would extend a little too far to the right with a hazy outline). In most cases there was an increase in the supracardiac shadow, apparently due to dilatation of the superior vena cava and to mediastinal involvement or displacement. The lung hilus shadows were increased in over half the cases (nine). In several (six) a clue was presented by the finding of considerable pleural thickening. The heart itself was more or less anchored in six cases, with or without restricted movements of the diaphragm on one side or the other. Pericardial calcification was noted by X ray in six of the 15 cases, but before operation in only three of the 12 cases that were operated upon. The presence of calcification is a helpful confirmatory sign, but it is usually absent, and when present it does not mean Pick's disease if there are no other evidences —pericardial calcification by itself does not indicate the need of surgery.

Electrocardiography.—Much help has come from the electrocardiogram, especially in doubtful cases. In all of the 14 cases electrocardiographed the record was abnormal in one of two respects: there was either low voltage (in five) or inversion or flattening of the T waves in Lead 1 or Lead 2 or both leads (in ten) —in one case both these anomalies were present. The inversion of the T waves was of the so-called coronary type, like that also found in many cases of acute pericarditis. The heart-rate varied widely. Normal rhythm was the rule, but auricular fibrillation was present in four of the 15 cases. It is of interest that the electrocardiographic abnormalities may persist in whole or in part after operation, even in the cured cases—in fact a complete return to normal has, in our small series of cases, occurred once only, namely in Case 4, in which after operation the electrocardiogram was perfectly normal. The reasons for the occurrence of the abnormalities and for their persistence are still obscure.

The *blood* frequently showed slight anæmia and usually but not always a low serum protein. A frequent figure for the serum protein was 3·5 to 4·5 milligrammes per cent. with increase after the correction of the trouble. The lower readings were found in the more chronic and sicker patients and were dependent probably on the combination of general malnutrition and the loss of protein in the ascitic fluid.

The *liver function* was sometimes slightly reduced. The urine was generally normal.

Differential Diagnosis

In the differential diagnosis of chronic constrictive pericarditis the following conditions must be taken into consideration, arranged in order according to their likelihood of confusion: mitral stenosis, polyserositis, cirrhosis of the liver, nutritional or other œdema, mediastinal tumours, tricuspid valve disease. According to my experience only the first four named conditions are likely to be confused with chronic constrictive pericarditis.

Mitral stenosis is to be differentiated by the finding of its characteristic diastolic murmur at the cardiac apex, in the absence of a severe active rheumatic infection. The presence of mitral stenosis may be taken at once as ruling out chronic constrictive pericarditis of any serious grade. Two cases have been sent to me in the last year for consideration of pericardial resection who showed on careful study mitral stenosis, confirmed at post-mortem examination; we recognised clinically the true state of affairs and so did not operate on these cases. The error in diagnosis had resulted from the finding of chronic preponderant abdominal enlargement (big liver and ascites) with engorgement of neck veins plus the failure to discover the characteristic diastolic murmur of mitral stenosis. The error of omission in these cases was due to the fact that auscultation had not been practised in exactly the right spot, that is, at the cardiac apex which happened to be far out in the anterior axillary line. The very fact that the heart was much enlarged in both these cases was in itself sufficient to rule out the diagnosis of chronic constrictive pericarditis as the fundamental condition.

Polyserositis.—A very common misunderstanding has been to confuse polyserositis with Pick's disease; mixed up in this confusion has been a general erroneous viewpoint concerning perihepatitis or iced or frosted liver (Zuckergussleber of Curschmann).[13] Polyserositis, or an inflammation of several serous cavities, sometimes called Concato's disease,[11] is occasionally found in young individuals, due to tuberculosis, associated with pneumonia, or, most commonly of unknown cause. The pleuræ and pericardium are the serous cavities generally involved, but sometimes the peritoneum is also affected. The infection begins as an acute process, sometimes insidious and obscure with little clinical evidence and sometimes severe and easily diagnosed; it goes on to a chronic fibrous state of varying importance. Polyserositis is not Pick's disease, although it may be the infection that precedes it in some cases. Neither is Pick's disease polyserositis, although the two frequently coincide. Chronic pleuritis of considerable degree occasionally accompanies chronic constrictive pericarditis, as does also chronic peritonitis. Perihepatitis resulting in the frosted or iced liver (Zuckergussleber), first clearly discussed by Curschmann,[13] may or may not be found in Pick's disease; it is not a necessary part of the disease. If there has been enough peritonitis during the polyserositis that may precede Pick's disease, then the liver may become frosted, or the spleen, or even the intestines, but in our series of cases among six whose livers were seen at necropsy (four patients) or at operation (omentopexy in two patients) there was chronic perihepatitis (icing or frosting) in none, that is, the liver capsule happened to be smooth and relatively thin in all, even though the liver showed considerable nodular fibrosis in one of them and was slightly nodular in two others. The most common site apparently for the chronic peritonitis is the under surface of the diaphragm; this was found in two of the six cases mentioned above (one at post-mortem examination and one at operation.) There has arisen a question as to the possible influence of the blocking of the lymphatic flow in that region to help to explain the persistence of the ascites in some cases. Perihepatitis, perisplenitis, and even frosting of the intestine itself may occur quite independently of pericarditis or pleuritis; they may be found associated or as isolated lesions.[4]

Portal cirrhosis of the liver should be easily distinguished from chronic constrictive pericarditis in nearly every case. The relative youthfulness of the patients with Pick's disease, their absence of a history of alcoholism or serious infection or other factor pointing to cirrhosis of the liver as the chief lesion, their small often "paradoxical" pulse with low pulse pressure, and particularly the apparently conclusive finding of increased pressure in the neck veins quickly distinguish them from cases of primary cirrhosis of the liver. The changes in the liver in most cases of chronic constrictive pericarditis are relatively slight and consist of vascular congestion plus the so-called cardiac cirrhosis, fibrous strands radiating from the central veins towards the interlobular spaces. The more chronic severe cases show a larger amount of this fibrosis, but not the degree of liver damage seen in primary cirrhosis of the liver. One of the five cases of our series (Case 13) whose liver tissue was examined, showed a high degree of cirrhosis which our pathologist (Dr. Tracy B. Mallory) believes to have been largely independent of his chronic constrictive pericarditis and to have been an important factor in hastening his post-operative death. His age was 52 years. Two other cases, a man (Case 11) and a woman (Case 12) both with severe symptoms and signs of chronic constrictive pericarditis over an interval of several years, showed a considerable degree of liver fibrosis, probably the result of an advanced chronic constrictive pericarditis. Most of the cases have some slight reduction of liver function as shown by special tests (such as with Rose Bengal or bromsulphalein), but not the high degree of dye retention found in the presence of jaundice or in a few cases of severe portal cirrhosis of the liver.

Nutritional œdema is easily distinguished from chronic constrictive pericarditis. It presents quite a different picture save for the generalised œdema, which may occur in some cases of Pick's disease, and the lower serum protein (below 5 per cent.) also found in some cases of Pick's disease, particularly in those with chronic malnutrition. The increased venous pressure, preponderant liver enlargement, and course of the illness quickly label as such the patients with chronic constrictive pericarditis.

Prognosis

The prognosis of Pick's disease without surgical treatment is unfavourable for health and in some cases for life. It tends to be a chronic disease, lasting several to many years, and often remaining at a standstill for long intervals of time. In a few instances as in several of our series, the downhill course may be rapid, ending in death from the disease itself or from complications in the course of months or a year or two. Remissions may occur, especially if favoured by therapy such as rest, diuretic drugs, and fluid and salt restriction, as pointed out in his own noted case by Finsen[16] 35 years ago. Spontaneous cure probably does not exist; surgery affords the only real cure, which in our experience has been effective for at least seven years.

The occasional cases of apparent recovery for intervals of months or years after the occurrence of symptoms and signs of cardiac compression before a recurrence of persistent symptoms and signs of much the same sort are undoubtedly to be explained as having had, at first, an acute pericarditis with effusion which subsided, and later on, after healing, constriction from a chronically contracted fibrosed pericardial sac (with or without calcification, which is in large part incidental).

Treatment

The so-called *Delorme operation*,[14 32] of pericardial resection is the only cure for chronic constrictive pericarditis or Pick's disease. It is evident that Brauer's simple operation[5] of removal of ribs over the heart, once called cardiolysis but better designated thoracolysis, cannot help in the least in freeing the heart from its shell of fibrous pericardium, although this operation may be useful in rare cases where there are important external adhesions glueing the heart to the chest wall itself, or in patients with very large hearts which raise the ribs in systole and not only increase their work thereby but cause much precordial discomfort.

There are four essentials for a successful operation of pericardial resection: (1) the evaluation of symptoms and signs that makes the diagnosis certain, (2) the selection of a case that is more or less crippled and yet a reasonable risk for the extensive operation that is necessary, (3) an expert anæsthetist (our cases have had general anæsthesia under ether), and (4) an experienced thoracic surgeon who is bold and yet cautious, who will do enough to free the heart and yet not too much to endanger the patient's life. It is possible to operate more than once to free adhesions and in at least one case on record the posterior surface of the heart has been successfully decorticated in a second operation after the anterior surface of the heart had been freed in a first operation. The commonly expressed fear that constricting adhesions once removed may reform has proved entirely groundless not only in our experience at the Massachusetts General Hospital but in that of others, in the absence of an acute or subacute pericarditis. When a second operation has been done at the site of an early resection the approach to the heart has been easy and rapid, only unimportant non-constricting adhesions having developed; the border of the unresected thickened constricting pericardium is easily identified.

THE STEPS OF THE OPERATION

In brief, the operation,[10] under ether anæsthesia, consists of the exposure of the pericardium and heart by the removal of the fourth, fifth, and sixth left costal cartilages and rib ends by costotome, and of the left part of the sternum by a special knife. The left pleura is identified and retracted; it is frequently adherent and sometimes extends unusually far to the right. The left border of the right pleura underlies the sternum and must also be looked for prior to beginning the pericardial dissection in that region. When the pericardium is reached it is scrutinised and opened at the most favourable point. In some cases there are only slight adhesions at the cardiac apex or along the left heart border or elsewhere, and the sites are then to be selected for the beginning of the dissection; in other cases the pericardium is closely adherent and calloused or even calcified over the entire surface of the heart, and then the dissection may begin in any convenient area, and may be continued more or less radially. It is best, so far as it is possible, to free the left heart chambers before the right, so that there may not be a flooding of the pulmonary circulation when the right chambers are freed first while the left chambers remain constricted.

The vital part of the operation—*that is*, the decortication of the heart—begins after about an hour's preparation of the field. Both blunt dissection and sharp dissection are used to free the heart itself from the constricting pericardium, which may be thick tough parietal pericardium, dense epicardium, or both securely or even inseparably united. Sometimes a line of cleavage is easily found but often it is not and one must then use great care to avoid splitting the muscle itself and entering one of the heart chambers, the right ventricle or right auricle in particular. However, even if the heart is penetrated the wound may be quickly repaired, as happened in two of our own successful cases (Cases 2 and 5); leaving a strip of pericardium attached to the heart as one dissects permits its use as a patch of tissue to suture over the wound. The thickened, or even calcified, pericardium is cut away in rather small pieces (averaging about 1 to 4 square c.cm. in area) while the dissection is in progress. In the usual course of operation the cardiac apex, the anterior surface of the right ventricle, the anterior surface of the right auricle, as much of the diaphragmatic surface of the heart as can be reached, and the inferior and superior venæ cavæ are freed so far as possible, in the order named. The dissection takes about an hour. The thoracic muscles and overlying tissue and skin are then sutured in place over the heart, and the patient is returned to bed to remain under an oxygen tent for as long as may be deemed necessary. My colleague, Dr. E. D. Churchill, plans to publish the details of his operative experience in these cases. Without his invaluable assistance I could not have so quickly collected data from proved cases relative to the diagnosis of chronic constrictive pericarditis. I take the greatest pleasure in acknowledging my indebtedness to him.

Two methods of treatment of chronic constrictive pericarditis which should be discarded because of their ineffectiveness, evident both in theory and practice, are: (1) digitalis therapy, and (2) omentopexy or the Talma operation.

Summary and Conclusion

A study of the literature and an analysis of a series of fifteen personal cases of chronic constrictive pericarditis, or Pick's disease, have shown that in the diagnosis one should take into consideration not individual signs alone but the entire clinical picture and history of the case. The leading clues are the result of "inflow stasis," namely, (1) the insidious onset of dropsy in a young person, (2) preponderant liver enlargement and ascites, (3) increased prominence of the jugular veins, (4) normal or relatively normal heart in the presence of dropsy without nephritis, and (5) low blood and pulse pressure and paradoxical pulse. Other important clues are (6) X ray evidence (poor pulsation, calcification, chronic pleuritis), (7) electrocardiographic abnormalities (low voltage or "coronary" T waves in chronic disease in early youth), and (8) a previous history of acute pericarditis or polyserositis.

Chronic constrictive pericarditis has been confused with four other conditions, but with ordinary care and thought such errors of diagnosis should not arise. The four conditions are mitral stenosis, polyserositis (including instances of perihepatitis or frosted or iced liver—Zuckergussleber), primary cirrhosis of the liver, and nutritional œdema. Two other conditions—namely, tricuspid stenosis and mediastinal tumours—may also cause some of the same signs.

The prognosis of cases with chronic constrictive pericarditis for good health is poor unless suitable for, and submitted to operation, although mild or only moderately severe cases may live for many years a semi-invalid life requiring much rest and frequent or occasional abdominal paracenteses.

Cure is now possible by surgery and an imposing number of successful cases of pericardial resection (by the Delorme operation, and not by that proposed by Brauer) is being accumulated. In our own clinic twelve cases have had this operation performed, ten by one surgeon; of these latter ten cases, six have been completely cured and one other relieved to a high degree. The first successful case in America, operated on seven years ago in 1928,[10] belongs to this group; this patient, a young woman, is in excellent health to-day, as are the other five cases of complete cure.

In closing, I would emphasise, that these are but progress notes; much yet remains to be learned about this important subject, but the obscurities are certain to yield to a richer experience.

KENT AND SUSSEX HOSPITAL.—A sum of £15,000 is needed to wipe off the debt on the building fund of this hospital. There is an average of 190 patients in the wards and a waiting-list for more. The total receipts for the half year were £12,400, and expenditure was £13,726.

THE TREATMENT OF OBESITY*

y JOHN H. ANDERSON, C.M.G., C.B.E., M.D. Melb.
PHYSICIAN, RUTHIN CASTLE, NORTH WALES

OBESITY is a symptom, not a disease, and the first tep in its treatment is to determine whether the ain causative factor is exogenous or endogenous. n most cases of obesity, and always in those of xogenous origin, food intake exceeds energy output nd the rational line of treatment is to decrease food nd increase muscular activity. Endogenous obesity alls for substitution therapy, for the governing efect in metabolism arises from dysfunction in ome part of the endocrine system, notably the hyroid, pituitary, or sex glands. Mixed types, ossessing both exogenous and endogenous features, re numerous and require a combined line of therapy. t is necessary at the onset therefore to take a careful istory, with especial reference to the patient's abits of life, food, and exercise and the occurrence f obesity in close relatives. A full clinical examinaion should also be made, reinforced where possible y laboratory tests, particularly a sugar-tolerance urve, an estimation of the basal metabolic rate, and radiological examination of the pituitary fossa. n each case there is, in my opinion, a second mportant point to be decided if treatment is to e successful. Is the patient healthy, apart from the emporary impairment of function due to fat infiltratng or accumulating on vital organs, or is there a owering of general efficiency due to associated disease n other systems, particularly the circulatory and the espiratory ? The two following cases illustrate this point.

A man in the sixties whose business forces him to lead n unhygienic life as regards food and exercise has paid everal visits to Ruthin Castle in the last few years. Apart rom his overweight he is in good condition and so can tand strict diet and vigorous exercise. In 183 days of treatment he has lost 168 lb. in weight, an average daily loss of 0·9 lb. Weight has been regained between treatments and he is now 12 lb. heavier than when first seen, though he has lost just 12 st. under treatment in the intervening period. He belongs to what I would call the "healthy or simple" obesity type.

Another man of about the same age was admitted with fibrositis, brachial neuritis, a blood pressure of 200/100, marked glycosuria, and a blood-sugar ranging from 0·18–0·24 per cent. His weight was 12 st. 7 lb. and under treatment it fell 14 lb. in five weeks, an average daily loss of 0·4 lb. On leaving, the blood pressure was 160/90, the blood-sugar 0·13–0·14 per cent., and he was free from pain in the arm and sugar in the urine. This patient typifies "unhealthy or complicated" obesity.

Treatment was on the same general lines in both cases but there was difference in detail, particularly as to rate of reduction, and in each case the final result was satisfactory.

It is the failure to recognise the possible association of obesity with lowered bodily efficiency and resistance that leads to unwished-for results and even tragedy. This is seen where loss of weight is too rapid and in the reduction often carried out by patients themselves, without proper supervision and by unsuitable means. For example, a man nearing seventy who was bronchitic and arthritic as well as obese, was treated elsewhere, with strict diet, internal and external douchings, purgation, and massage. He lost 2½ st. in under a month, but was laid up most of the next four months with his joints and chest, and when he had "recovered" from his "cure" found to his disgust that he had regained most of the lost weight. We found that it was possible to produce more permanent results by less drastic methods. It is to be noted in passing that the weight lost in these rapid reductions is almost as rapidly regained. If the patient is to remain well he must acquire a mode of life, particularly as regards food, which will enable him to keep his appetite and so his weight within bounds. This takes time and too rapid reduction often defeats its own ends. In the great majority of the cases, with which we as medical practitioners have to deal, reduction is not undertaken with a view to producing spectacular results as shown by a weighing machine, but to increase the efficiency and well-being of our patients. Obesity has been described as falling into three grades according to its severity—the enviable or regal, the comical, and the pitiable. Our duty is to restore our patients to the normal.

Four Lines of Attack

In the direct treatment of obesity there are four lines of attack: two major, (1) diet, (2) exercise; and two minor, (3) drugs and (4) physical treatment. Except in some cases of endogenous obesity, diet and exercise are of paramount importance.

DIET

It is a common belief that a successful reduction diet must, of necessity, be unpalatable, unpleasant, and unsatisfying. This need not be so, provided care is taken in the selection of the component foodstuffs and variations are allowed for. Sir Edmund Spriggs, a pioneer of the measured and varied diet in obesity, made this clear enough when addressing[1] the Medical Society of London in January, 1929. "If," he said, "the amounts are measured there is hardly any food which may not be allowed—at least in small quantities. . . . It is essential to teach the patient that it is the total caloric value which counts, otherwise he runs away with the idea that some foods are fattening and that others, such as fruit, toast and biscuits of protein or rye are not, and that an obese person can be reduced by permitting this and forbidding that, irrespective of amount."

Many types of diet are described, varying in their composition, attractiveness, and reliability. One well-known American diet is made up of fruit and vegetables, bran, gluten bread, cheese, and buttermilk. Another somewhat similar one, which I have seen give good results, allows for breakfast: dried bread, fruit, milk, and tea; for lunch: omelette, salad, fruit, and dried bread; only tea and skim milk at teatime; and for dinner: steak, fillet of beef or chop, salad, and dried bread. The danger with the somewhat bizarre diets is that "after the cure" the patient is tempted to return to his fleshpots with renewed vigour. Mere reduction of quantities is not enough and a well-balanced reduction diet combines considerable protein, reduced carbohydrate and fat, made up of foodstuffs chosen so as to provide a bulky vehicle. Excess carbohydrate is often the cause of the obesity, but it should not be reduced so as to make the diet unpalatable, the patient lose energy or develop an acidosis. Vegetables and fruit make for bulk and are a convenient way to give carbohydrate; they also help in preventing constipation. Enough protein should be given to balance the loss of body protein due to daily wear and tear. This can be done in the early stages of reduction, but it is difficult to provide the necessary two to three ounces when the daily intake falls below 900 calories. The body loses weight by the oxidation of its fat and the release of water. Fat in the food is therefore strictly rationed, allowing enough to supply the necessary fat-soluble vitamins. It is interesting to compare the number of calories derived from carbohydrate, protein, and fat respectively, in an ordinary diet of 2600 calories and in a reduction diet of 1300 calories. In the ordinary diet caloric proportions are carbohydrate 55 per cent., protein 14 per cent., fat 31 per cent., and in the reduction diet, carbohydrate 34 per cent., protein 33 per cent., and the fat 33 per cent. In reducing the nutritive value of the diet by one-half the proportion of carbohydrate has been notably decreased, the proportion of protein greatly increased, and the proportion of fat is almost unchanged.

---

* The substance of this paper was contributed to the discussion on obesity held by the section of medicine at the annual meeting of the British Medical Association at Melbourne on Sept. 11th.

Patients often ask how much water they may drink. If there is associated circulatory disease the amount should be kept low, but otherwise, on a weighed diet, no restrictions need be imposed. When the food is not weighed fluids are taken at the end of a meal after all the solid food has been eaten. There are certain precautions worth taking in the preparation of food. Butter and lard should not be used in cooking, fried foods should be avoided, lean meat should be chosen and it is best roasted or grilled. Tinned fruit should be washed in three or four changes of water and fresh stewed fruit sweetened with saccharin, which, in liquid or tablet form, provides a suitable substitute for sugar in a reduction dietary.

At Ruthin Castle, for convenience in working, we have a number of carefully balanced diets, ranging in caloric value from 1400–500 calories a day (List 1). In use these standard diets are regarded as a basis, and are varied in most instances to meet the needs and idiosyncrasies of individual patients. It may be necessary to replace one foodstuff with another more palatable one, or even to rearrange the whole day's menu so as to approximate as closely as possible to the meals the patients will take on leaving the clinic (Lists 2 and 3). It is important for the patient to be kept contented and not irritated by the restrictions imposed, and at the same time trained so that he may continue the régime in a modified form on his return to everyday life.

STANDARD DIETS

LIST 1

Ruthin Castle Standard Reduction Diets

Weights are given in grammes (30 g. = 1 oz.)

LIST 2

Example of a Diet of 1500 Calories (approx.)

In each list weights are given in grammes; ounces in parentheses.

Breakfast.—Grilled fish 120 (4), grilled fish 75 (2½) and one egg, bacon 20 (⅔) with tomato 90 (3), cold ham 60 (2), bacon 15 (½) and one egg or two eggs; toast 30 (1), butter 10 (⅓), sugarless marmalade 15 (½), milk 45 (1½), tea.

Dinner.—Roast beef or roast mutton (hot or cold) 90 (3), grilled steak, boiled beef, grilled chop, boiled mutton, roast turkey or chicken 105 (3½), veal 120 (4), grilled sweetbreads 90 (3) with bacon 20 (⅔), or liver 90 (3) with bacon 10 (⅓); vegetables (excluding potato) 120 (4) or salad (without dressing) 120 (4); stewed fruit 90 (3) or fresh fruit 120 (4); toast 30 (1), butter 10 (⅓).

Evening.—Fried fish 105 (3½) or meat as at dinner or scrambled eggs, two; vegetables and salad and fruit as dinner; cheese 30 (1); toast 30 (1); butter 10 (⅓); milk 45 (1½); tea. If vegetables are omitted toast may be increased to 40 (1⅓).

Supper.—Two water biscuits; milk 30 (1); tea.

LIST 3

Example of a Diet of 1000 Calories (approx.)

Breakfast.—Grilled fish 120 (4), grilled fish 75 (2½) with one egg, bacon 20 (⅔) with tomato 90 (3), cold ham 60 (2), bacon 15 (½) and one egg, or two eggs (boiled or poached); toast 15 (½); butter 5 (⅙); sugarless marmalade 15 (½); milk 45 (1½); tea.

Dinner.—Roast beef or roast mutton (hot or cold) 60 (2), grilled steak, boiled beef, grilled chop, boiled mutton, roast turkey or chicken 75 (2½), veal 90 (3), grilled sweetbreads 90 (3) with bacon 10 (⅓), or liver 105 (3½); vegetables 120 (4) or salad 120 (4); stewed fruit 90 (3) or fresh fruit 120 (4); toast 15 (½); butter 5 (⅙).

Evening.—Fried fish 75 (2½) or meat as at dinner or two eggs (boiled or poached or as omelette); vegetables, fruit, toast, and butter as dinner; milk 45 (1½); tea. If vegetables are omitted toast may be increased to 30 (1).

Supper.—Two water biscuits; milk 30 (1); tea.

LIST 4

Instructions Given to Patients on Leaving Hospital

The diet should be made up as far as possible from fish, eggs and meat (except as stated below), green vegetables, parsnips, carrots, turnips, celery, mushrooms, cauliflower, onions, tomatoes, beetroot or salad, stewed and fresh fruits. Bread, toast, rusks, water biscuits, butter, cream, and cereals should be taken in small quantities only.

Foods to be avoided are: sugar, puddings, creams, cakes, sweet biscuits, shortbread, and nuts.

Salmon, herrings, pork, duck, bacon, savouries, rich sauces, potatoes, cheese, and made-up dishes such as pies, fricassées, rissoles, sausages, and macaroni cheese, which are concentrated foods, should be taken sparingly.

So far as possible no fluid should be drunk during meals until all the solid food has been eaten. A daily walk should be taken out of doors.

Example of a day's diet.—The food need not be weighed, though an occasional check is advisable; weights used in an average diet are given in grammes (30 g. = 1 oz.) and in ounces (parentheses).

Breakfast.—Grilled fish 120 (4), fish 75 (2½) and one egg, bacon 15 (½) and one egg, cold ham 30 (1) and one egg, two eggs, or bacon 30 (1); bread 20 (⅔); butter 5 (⅙); sugarless marmalade 15 (½); milk 60 (2); tea or coffee.

Lunch.—Fish 120 (4) or meat 60 (2); two vegetables 75 (2½) of each or salad 120 (4); unsweetened fruit 90 (3) or fresh raspberries, strawberries, gooseberries, or melon 200 (6⅔), greengages, peaches, nectarines, grape fruit, or orange 150 (5), cherries, apples, pears, plums, or grapes 120 (4), banana or figs 60 (2); bread 20 (⅔); butter 5 (⅙).

Tea.—Bread or water biscuits 15 (½); butter 5 (⅙); sugarless jam 15 (½); milk 45 (1½); tea.

Dinner.—Clear soup or soup made from vegetables only; fish 40 (1⅓); meat, vegetables, and fruit as at lunch; bread 20 (⅔); butter 5 (⅙).

Bread or toast should not exceed 75 g. (2½ oz.) and butter 20 g. (⅔ oz.) in the day. The body-weight should be taken regularly once a fortnight and an increase on two successive weighings followed by a stricter diet.

In deciding the caloric value of the diet with which to begin, attention is paid to previous habits as regards food and exercise and to the present physical condition. Each case must be judged on its merits, remembering that it is better to give too much in the early stages rather than too little. When a base line has been established the diet can be altered as required, preferably on the day of the weekly weighing, taking into consideration the general condition of the patient as well as the change of weight shown by the scales. It is rather astonishing what a difference can be made by slight modifications. Thus a glass of milk and a biscuit several times a week in the dietary of a man leading a regular life as regards food and exercise produced a gain of half a stone in six months, and it took nearly the same time for the original weight to be regained after the extra food was omitted. At Ruthin Castle the lowest standard diet is 500 calories a day. Cases are reported however where patients are said to have gone for months on a daily intake of under 400 calories, without ill-effects.[3]

Once patients have begun treatment they are anxious to lose weight quickly and try to stampede their medical adviser into arranging "starvation days" or "fast days" and the like. As a rule they require protection against themselves in this respect. Fluid days have their place in treatment, particularly in the early stages and again when the flabby fat has been got rid of and the weight tends to be stationary on a low diet and adequate exercise. A diet suitable for a fluid day may be made up as follows :—

Soup (clear stock soup, chicken tea or broth, marmite soup, oxo, bovril, &c.) or the juice of two oranges in a little water at 11 A.M., 1 P.M, 6 P.M., and 8 P.M., varied with tea and a little milk or lemon at 8 A.M., 4 P.M., and 10 P.M. In addition, water or simple lemonade may be taken as desired. On a soup day the patient receives 62 calories if whole oranges are given instead of the juice only, the caloric value rises to 410 and on the orange day 162 calories. According to his condition the patient on a fluid day takes full or reduced exercise or spends the day quietly in bed. If there is any doubt as to stamina, fluid days are best omitted and in any case should not be allowed more than once in seven or ten days.

To obtain the best results close coöperation and frankness between patient, doctor, and dietist are essential. "Breaking diet" is the great temptation and often great tact is required to prevent it. Hunger between meals can generally be appeased by a breakfast cup of clear soup and if this is not enough a slice or two of cold lean meat is given. Cold meat is preferable to hot as it is more readily available and more easily cleared of its surplus fat. In hospital the food can be supervised, varied, and weighed in a way not possible in a private house, and to counteract this as far as possible each patient, on leaving, is given written instructions for his guidance (List 4).

EXERCISE

Exercise should be prescribed as carefully as diet and consists for the main part of walking, putting, golf, and even tennis in suitable cases. Here also it is wise to begin quietly and increase gradually according to the weight lost and the response shown in the patient's general condition. The difference of pulse-rate and blood pressure before and after exercise is of great value in gauging how much a patient is capable of, and how much is good for him. Healthy tiredness is good, but exhaustion and fatigue are to be avoided. Exercise should be regular and steady and it requires constant supervision and encouragement to ensure this. A walk in the morning and some game in the afternoon is a good arrangement and a variation may be made by taking a 'bus or car in one direction and walking the other. The stiffer part of the walk, against the wind or uphill, should be done on the outward journey when fresh, and as a general rule walking alone is to be preferred.

The patient should be encouraged to regard his daily walk as an essential part of his treatment, which, if faithfully carried out, will produce a sense of mental and physical satisfaction in addition to melting his too solid flesh. Regular exercise demands regular rests, and periods of activity and inactivity should alternate. A good plan is to exercise in the morning and afternoon, with a rest after the midday meal and again before the evening one. This is difficult to arrange in ordinary life, but a useful substitute will be found in walking part of the way to and from the office or train, morning and evening, with a quiet time after the midday meal. Strenuous or "potted" exercise at week-ends, after a sedentary week, often does more harm than good and the same criticism applies to vigorous exercise before breakfast, though it suits some people. Before sanctioning either of these measures the doctor should satisfy himself that it is in the interest of the patient. Moderate exercise increases body metabolism three times and severe exercise nine times,[4] and with obese patients on active hospital treatment an occasional slack day is good policy: allowing a motor run, visit to a cinema, or something similar to replace the usual outdoor routine. It makes a pleasant break and prevents staleness. To take severe or even moderate exercise on a reduction diet calls for courage and determination, and as the labourer is worthy of his hire so is the hard-working reduction patient deserving of his occasional day of rest.

DRUGS

On theoretical grounds drugs should be the sole treatment necessary in endogenous obesity, and where hypothyroidism is the cause this is so, thyroid being specific. Rigid dieting is not required in these cases and as a rule is badly tolerated. In the other types of endogenous obesity the results from glandular therapy alone are uncertain and generally disappointing. This may be due to the unsuitability of the preparations at our disposal coupled with our incomplete understanding of the functional interlocking of the ductless glands. Where the obesity is genital or pituitary in origin we use diet, exercise, and thyroid, adding pituitary extracts in the pituitary cases and controlling the dosage by estimation of the basal metabolic rate and sugar tolerance. The evening pulse, if taken regularly, is a simple and useful guide in thyroid medication, as a rise of 10 to 15 beats per minute points to overdosage. In exogenous obesity and in many cases where an endocrine element may be suspected, but cannot be proved, thyroid plays an important part. When the weight tends to become stationary and it is thought unwise to decrease diet or increase exercise any further, a small dose of thyroid (gr. ¼–1 of the dried extract) should be given twice a day, unless some contra-indication is present. If necessary the dose may be increased later up to grs. 2 or 2½, and I have never seen any ill-effects follow its use in this way. It is better not to let the patient know what he is taking, and it should be made quite clear that the drug is an adjuvant to, and not a substitute for, diet and exercise. Patients taking their own thyroid at home should be given a limited quantity at a time or instructed to omit it for the last ten days in each month. Unless under regular supervision they should be warned as to the early symptoms of hyperthyroidism. There is a danger of establishing thyroid addiction unless precautions of this nature be taken.

A woman, for social reasons, began to slim by the aid of thyroid without her doctor's knowledge or consent, and in three months lost over 4 st. in weight. She was admitted to Ruthin Castle with a pulse-rate of over 120 per minute and complaining of shortness of breath, general weakness, palpitation, and nausea. A week after withdrawal of the thyroid the pulse-rate was 80, the breathing normal, and weight was being gained. In the next few years she had several relapses, always due to self-prescribed thyroid, accompanied by congestive heart failure and finally auricular fibrillation and œdema. In one attack withdrawal of thyroid and administration of salyrgan raised the daily output of urine from 200 c.cm. to 4000 c.cm. and lowered her weight by 1½ st. in eight days.[5]

Certain dinitrophenol substances are being used in preference to thyroid as they are claimed to have a less disturbing constitutional effect. They are said to raise the basal metabolic rate but not to have any effect on pulse-rate or blood pressure. This would appear to be a disadvantage, as the pulse-rate is helpful in controlling this type of medication. The most useful sphere for pluriglandular extracts such as Hormotone and Iodobesin is where obesity is combined with menstrual or climacteric disorders. In glandular therapy, as with diet and exercise, it is wise to begin quietly and increase the dose according to the patient's loss of weight and general response.

PHYSICAL TREATMENT

The patient can be made more comfortable by certain forms of physical treatment, though their effect on the weight is almost negligible. Massage strengthens the muscles and so facilitates the taking of more exercise. The belief, so generally held, that "hard or deep" massage "breaks up the fat" and so reduces weight is in our experience a fallacy. The electric light bath, by producing a profuse diaphoresis, improves the feel of the skin and the general tone, but the weight lost as fluid is as a rule regained within 24 hours. The electric stimulus, arranged to make the muscles contract against resistance, as in the Bergonié chair, is stimulating and soothing and often induces sleep. It is of particular use when circulatory disease limits exercise.

Results

There are few chronic disabilities where so great an improvement in the well-being of the patient follows a good start on proper lines. On a controlled diet and graduated exercise patients benefit, even when no weight is lost, and the loss of a few pounds will make a difference to the comfort, quite disproportionate to the result shown by the scales. Here a word of caution is needed. In the first week on diet and exercise the patient feels lighter and brighter in every way and looks forward with every confidence to the next weighing. Unless a warning has been given there is often great disappointment when it is found that the loss is very small, perhaps under 1 lb. In one girl of 23 there was no loss of weight in the first six days, though she stated she felt "totally different." With no essential change of régime, 9 lb. was lost in the following three weeks and thereafter 2 lb. a week. With steady carefully controlled reduction much good can be done and the results at times are comparable to those seen in myxœdema after thyroid medication.

Thus a woman of 51 had deteriorated mentally and physically while gaining weight over four or five years. She was slovenly and even dirty in her personal habits, her speech had become coarse, her mode of life varied between senseless extravagance and equally needless parsimony, and she had to be helped in and out of bed. With diet, exercises, and later a small dose of thyroid (gr. ½ twice a day) her weight fell from above 18 st. to below 12 st. She could then walk four miles a day comfortably, was bright and cheerful, clean in person, dress, and speech, and was leading an ordinary life socially.

We consider a loss of 10–14 lb. a month as sufficient in uncomplicated cases, though there is great individual variation: 26 lb. was lost by one man in 20 days, including 10 lb. in the first six and a half days, but this is exceptional. The greatest loss shown in Ruthin Castle records for one continuous course of treatment was 12 st. This was in a man of 30 years of age, and took eight and a half months, his weight falling from 25 to 13 st. Women often hold their weight or even gain in the week before a period: this is generally followed by an extra drop once the menstrual disturbance is over.

Insistence on a salt-free diet does not seem necessary, but patients are generally advised to content themselves with the salt used in cooking and to add as little as possible at the table. Bread is often a difficulty, and if the limited amount allowed produces hardship the addition of casein bread will often solve the trouble. The state of the feet should be inquired into when considering exercise, as obese people are particularly subject to corns, weakness of the arches and ankles, and, at times, their inability to take exercise is due to this.

For example, a woman of 61 attributed her overweight to restricted exercise due to multiple callosities on the soles of both feet. She was put on a mild reduction diet and after the corns had been treated walking exercise was begun. During her stay in hospital she lost 30 lb. in weight and another 1 st. after her return home. When admitted 400 yards at a time was her limit, but later she walked two to three miles in comfort.

The urine of reduction patients should be examined regularly, and if acidosis appears the carbohydrate in the diet increased. In our experience this is rarely necessary though some physicians give glucose at intervals or daily alkalis as a safeguard. Constipation is more often seen, but an increase in fruit or vegetables with a teaspoonful of liquid paraffin twice a day is as a rule enough to overcome it. The weekly weighing day is the patient's dread and the physician's bugbear, and special care is needed after these occasions to ensure that the régime is not relaxed or made stricter unreasonably as a result of what the scales reveal. The habit of regular weekly or fortnightly weighings should be continued after leaving hospital and an increase in weight on two successive weighings calls for a stricter diet or a consultation with the patient's doctor.

Much can be done to improve the mental outlook and physical condition of the obese. As a rule they are outwardly cheerful but when their confidence is gained it is generally found that they regard their disability more anxiously and resentfully than appears to the casual observer. With careful treatment and steady encouragement they respond well and "one is astonished at the unanimity with which patients report a return to vigour, a feeling of well-being and resistance to fatigue which has been lost for months or years."[3] Such a therapeutic result is worth working for.

OBSERVATIONS UPON BILIARY DRAINAGE

By Thomas Hunt, D.M. Oxon., F.R.C.P. Lond.
PHYSICIAN TO OUT-PATIENTS, ST. MARY'S HOSPITAL, LONDON; LATE MACKENZIE-MACKINNON RESEARCH FELLOW

Much has been written on the technique and also on the diagnostic and therapeutic uses of biliary drainage. The present paper, based on over 100 cases in which it was used, makes no claim to review all these aspects of the subject. The group of cases analysed are selected from a much larger number, and form a series in which the diagnosis was definite and the biliary stimulus always the same—namely, 50 c.cm. of 33 per cent. warm magnesium sulphate solution. Any cases in which the position of the tube in the duodenum has been uncertain have been excluded, and in some the drainage has been performed twice or even three times if the result has been doubtful.

Biliary drainage has been carried out, first, on a number of persons whose biliary and hepatic systems was presumably healthy. A few of these have had no illness; the others have been sufferers from arthritis (12), hyperthyroidism (5), iridocyclitis (5), Ménière's disease (2), and neurosis (5). For purposes of comparison I have regarded these as normals.

It might be supposed that the rate and volume of biliary flow would enable us to draw conclusions about biliary disease, comparable to those we draw from the flow of urine. That hope, however, has not been fulfilled. The onset and the amount of flow after the introduction of the stimulus give little indication whether disease is present or not (Table I.).

Table I.—*Average Onset, Rate, and Volume of Bile-flow* (74 *Cases*)

Type of case.	No.	Time to onset of flow.	Duration of flow.	Total bile flow.	Flow per minute.
		mins.	mins.	c.cm.	c.cm.
Normal patients ..	22	9	28	40	1·4
Pathological gall-bladder (cholecystitis)	16	6	24	50	2·0
Gall-stones ..	6	3	27	46	1·7
Liver disease ..	20	8	27	45	1·7
Cholecystectomy ..	10	7	14	40	3·0

Even with a seriously damaged liver (e.g., in advanced cirrhosis) bile is secreted after the injection of magnesium sulphate in about normal quantity after the normal latent period and at about the normal rate. On the other hand, the flow is certainly much faster after removal of the gall-bladder, and this suggests that the quantity and rate of flow, after the dose of magnesium sulphate, is governed less by the organic condition of the liver than by some controlling influence of the gall-bladder; the normal response to the introduction of magnesium sulphate seems to be an *emptying* of the gall-bladder and liver, and is not wholly dependant upon liver secretion.

Similarly it might be hoped that the symptoms produced by reflex stimulation of the biliary flow would give some indication of disease in the gall-bladder when this contracts and empties its contents. The symptoms, however, prove no certain guide (Table II.). A gall-bladder containing stones may empty its contents normally with no symptoms or discomfort, and this is of interest in relation to the causation of symptoms in cholelithiasis. As a rule, however, there is considerable discomfort, and sometimes severe pain over the gall-bladder and in the right hypochondrium and epigastrium, during the flow. Patients who have had their gall-bladders removed are particularly apt to have severe nausea, discomfort, or vomiting while the flow is in progress. Also symptoms are about twice as common in chronic cholecystitis, and about four times as common in the presence of stones, as they are in the normal subject. Hence the course of the drainage should be carefully watched and noted. In severe cirrhosis of the liver there is rarely pain or discomfort, and in only 4 patients out of 21 suffering from hepatic disease was there vomiting during or immediately after the flow of bile.

Table II.—*Reaction to Introduction of Warm Magnesium Sulphate into Duodenum* (133 *Cases*)
(50 c.cm. of 33 per cent. solution)

Type of case.	No.	Showing symptoms.*	Showing no symptoms.	Per cent. showing symptoms.

Migraine patients ..	41	16	25	39

* Nausea, pain, discomfort, vomiting.

Undue stress should not, however, be laid on these findings, owing to the unavoidable psychological effect of carrying out the test. (Special care was taken in these cases not to let the patient think that anything other than water was being injected down the tube.) It is known also that symptoms may vary with the type of stimulus employed so that from the diagnostic point of view results in different hands may be difficult to compare.

Another fact that is remarkable is that such a relatively large dose of magnesium sulphate introduced direct into the duodenum—about 4 drachms of the salt—causes nausea or discomfort in less than 1 in 5 normal subjects; and if the bile is removed by the tube it seldom produces much diarrhœa. The same dose introduced into the stomach usually causes profuse diarrhœa and, as would be expected, more nausea and vomiting. This observation suggests that part at least of the purgative effect of magnesium sulphate is dependant either upon the increased flow of bile into the intestine or upon the effect of the salt in the stomach where it may set up gastro-colic stimulation either chemically or reflexly.

Complete failure to obtain any bile after introduction of the magnesium sulphate is very rare, provided care is taken to ensure the correct position of the tube. In five patients only have I noted complete absence of any reflex biliary flow to this stimulus, though in no case was the test abandoned under 35 minutes, and in most cases not till a longer time had elapsed. (In 3 of these cases 1 c.cm. of pituitrin given subcutaneously also failed to bring about withdrawal of bile from the tube.) In all these there was no doubt about the position of the tube, but the only response to the introduction of the usual stimulus was a slow secretion of 15–20 c.cm. of thick mucoid white fluid, strongly alkaline, which I regard as pancreatic in origin.

Four of these five patients showed a curiously similar clinical picture. Three were female and one male. All were very neurotic and all complained of long-standing upper abdominal discomfort, with attacks of severe pain amounting to true colic, coming on two or three hours after food. Three of them were woken about 2 A.M. with severe pain, and all stated that they could not eat eggs or fat without discomfort or pain. In two cases the symptoms had followed a severe mental shock. Only three of these patients were radiographed after administration of tetraiodophenolphthalein by mouth and of these two showed no shadow of the dye; the third gave a normal concentration. One of the patients showing no dye shadow was operated upon later and the report was "enlarged gall-bladder; no stones; no inflammatory changes. Cystic duct constricted. Cholecystectomy performed." In this patient an eight-hour residue in the stomach was also shown by barium meal, without any evidence of any organic lesion.

I think that these five patients almost certainly belong to the group of functional spastic dyskinesias of the gall-bladder (Westphal, Newman), due to nervous causes, and in the absence of obstructive jaundice complete failure to obtain any bile is suggestive of such functional disorder of the biliary passages.

TABLE III.—*Concentrated "B" Bile*

Type of case.	No.	"B" bile.		Per cent. showing *no* "B" bile.
		Present.	Absent.	
Normal patients	22	19	3	14
Pathological gall-bladder (cholecystitis)	16	4	12	75
Gall-stones	8	3	5	62
Liver disease..	19	16	3	17
After cholecystectomy ..	10	0	10	100
Migraine patients	35	27	8	23

Failure to withdraw any concentrated "B" bile, which comes at least in part from the gall-bladder itself, has very much less significance however (again in the absence of obstructive jaundice). From Table III. it will be seen that in over 10 per cent. of normal subjects no gall-bladder (or "B" bile) was found. In none of 10 patients subjected to biliary drainage at periods from 3 months to 14 years after cholecystectomy was any true concentrated "B" bile obtained, though certain workers state that it may be recovered in a proportion of such patients (Martin).

In only about a quarter of the cases of gall-bladder disease have I obtained a normally concentrated "B" bile.

As a rule, when "B" bile is not obtained, the cholecystographic shadow is below normal; but there is a divergence of some 30–40 per cent. in my cases both in patients showing a normal shadow and those giving no shadow or an abnormally faint one. (Table IV.). The second group shows the diagnostic significance of a positive cholecystogram (absent or very faint shadow) combined with the withdrawal of a normal concentrated "B" bile. This is a highly characteristic finding in liver disease, and I have noted it in 7 cases of cirrhosis of the liver (4 of which were proved by operation). Such a combination is likely when the liver is so diseased that it fails to pick out the opaque dye from the portal circulation in sufficient concentration, whereas biliary concentration in the gall-bladder (being healthy) is unimpaired so that dark "B" bile is obtained by drainage. The use of the two methods in combination may therefore be worth while where cirrhosis of the liver is suspected. A further characteristic feature of severe cirrhosis of the liver is the striking appearance of the bile which has a bright red colour, unlike the normal yellow, brown, or dark mahogany tinge.

TABLE IV.—*Oral Cholecystography and Biliary Drainage*

Oral cholecystogram.	No.	Concentrated bile.	No concentrated bile.	Percentage agreement.
Normal shadow ..	20	12	8*	60
Absent or very faint shadow	25	8†	17	70

* 8 cases: 1 cholecystitis (oper.), 3 cholecystitis (?), 3 migraine, 1 normal.

† 8 cases: 7 cirrhosis of liver, 1 migraine.

As regards the chemical, microscopic, and bacteriological findings in bile, I only propose to mention two points. The first refers to the significance of crystals on microscopic examination, since some writers have regarded the findings of both cholesterol and pigment deposits together as pathognomonic of gall-stones (Bochus). Thus Piersol records that all his cases in which both crystals were found proved to have calculi; of 40 patients investigated by Rafsky, in whom both types of crystals were found in the bile, only 1 showed no calculi or cholecystitis at operation. The observation is one of considerable diagnostic importance, but there are a few records of the incidence of these crystals in the bile of normal people.

Table V. shows the microscopic findings in my patients, in all of whom the bile was examined soon after withdrawal—just as urine must be examined if significance is to be attached to crystalline deposits. In 9 out of 43 (21 per cent.) of my presumed normal subjects both types of crystals were present; they were also found in 10 out of 13 cases of proved gall-stones. (I have not attempted any quantitative comparison of the numbers of crystals.) From this it seems that the coexistence of cholesterol and

TABLE V.—*Crystalline Deposits in Bile* (91 *Cases*)

Type of case.	No.	Cholesterol only.	Pigment only.	Cholesterol and pigment.	No crystalline deposit seen.
		No. and per cent.	No. and per cent.	No. and per cent.	
Normal patients ..	43	14 (33)	18 (42)	9 (21)	1
Liver disease ..	14	1 (7)	5 (36)	5 (36)	3
Pathological gall-bladder (cholecystitis)	10	1 (10)	8 (80)	1 (10)	–
Proved gall-stones.	13	0	3 (23)	10 (77)	–
After cholecystectomy	11	2 (19)	1 (9)	7 (64)	–

calcium bilirubinate crystals cannot be regarded as pathognomonic of gall-stones, though strongly suggestive of that condition. It is significant that the proportion of cases showing both types of crystals was about the same after cholecystectomy (almost always for gall-stones) as in subjects of cholelithiasis which implies that there is some underlying abnormality of the bile in gall-stone subjects, apart from inflammatory changes in the gall-bladder itself.

The last point concerns the significance of protein in the bile, as tested by the very rough Esbach's estimation. I have found 0·5 part per 1000 represents an empirical normal level, and that the level is increased in more than half the cases of cirrhosis and other diseases of the liver, and also in about the same proportion of cases of gall-bladder disease. It appears that a marked increase of albumin in the bile may be due either to alteration in the secretion of bile by the liver, or to its concentration by the gall-bladder. In a number of migraine patients showing a *dense* shadow by cholecystography—which means that the concentration of gall-bladder bile is increased—the protein content of the bile was particularly high.

I do not think the protein content of the bile is of practical value in the diagnosis of gall-stones or cholelithiasis. In all cases the figures refer to the protein estimated in the most concentrated specimens of bile obtained in each case, though there is usually little difference in this respect between the various fractions of bile removed.

SUMMARY

(1) Observations upon biliary drainage in over 100 cases, using magnesium sulphate as a stimulus, are recorded. (2) The rate and volume of biliary flow gave no indication as to the condition of the liver, gall-bladder, or biliary passages. (3) Pain, nausea, and other symptoms were observed during the flow of bile in 16 per cent. of normal subjects, but more frequently in the presence of gall-bladder disease. (4) Failure to obtain any bile by drainage, in the absence of jaundice, was rare (5 cases only); dyskinesia of the gall-bladder is suggested as a cause in some of these patients. (5) In 10 per cent. of normal subjects and 75 per cent. of cases of gall-bladder disease no "B" bile could be withdrawn. (6) Results are compared between oral cholecystography and biliary drainage in 45 cases; failure to visualise the gall-bladder by oral cholecystography, in association with the finding of "B" bile by drainage, was found to be characteristic of liver disease. (7) Calcium bilirubinate (pigment) and cholesterol crystals were found together in the bile in 21 of normal subjects and 77 per cent. of gall-stone subjects.

My thanks are due to the trustees of the Mackenzie-Mackinnon Research fellowship; also to Dr. H. Orton and Dr. Courtenay Gage for very kindly carrying out the radiographic examinations, and to my colleagues at St. Mary's Hospital for allowing me to investigate patients under their care.

A CASE OF AGRANULOCYTIC ANGINA

BY B. J. BOULTON, M.B. Brist.
ASSISTANT RESIDENT MEDICAL OFFICER, HAM GREEN HOSPITAL AND SANATORIUM, BRISTOL

A WOMAN aged 47, unmarried, was admitted to Ham Green Isolation Hospital (Bristol Public Health Department) on May 24th, 1935, the case being notified as one of suspected faucial diphtheria.

History of illness.—She first consulted her doctor on April 2nd, 1935, complaining of a sore-throat which developed by the 5th into a definite follicular tonsillitis. Swabs taken were returned negative. The throat condition did not clear up until April 14th. On May 21st there was a recurrence rather worse than the previous attack, which rapidly became more severe. On May 23rd an area of inflammation appeared on the dorsum of the left hand.

On admission (May 24th) the general condition was poor and the patient appeared to be acutely ill. The temperature was 103° F., the pulse-rate 128, and the respirations 28. Tongue furred. The fauces showed yellow semi-membranous sloughs with very little inflammatory reaction apart from narrow areas of erythema around each. Heart sounds poor, lungs normal; the spleen was not palpable and there was no jaundice. The urine contained a trace of albumin. The lower part of the nose was inflamed and swollen, and the dorsum of the left hand and lower forearm showed a large inflamed area with a blackish superficial necrosis and no attempt at pus formation. The surrounding tissues were soft. Antistreptococcal serum (20 c.cm.) together with antidiphtheritic serum (800 units) was administered intramuscularly.

Progress.—By the following day (May 25th) there was no improvement in the patient's condition and the possibility of this being a case of agranulocytic angina was discussed. A leucocyte count gave a figure of 625 per c.mm. Examination of blood films revealed an obvious neutropenia; some of the smears showed less than a dozen white cells in all and these were chiefly lymphocytes. A differential count, based on 50 cells only, resulted as follows:—

Polynuclears	6 %	Transitionals	6 %
Small lymphocytes ..	66 %	Eosinophils	0 %
Large lymphocytes ..	22 %	Basophils	0 %

Arneth count impossible. Red cells appear normal.

As supplies of *pentose nucleotide were not* immediately available, sodium nucleinate in doses of gr. ¾ were administered intramuscularly at four-hourly intervals. On May 27th (after 12 doses of sodium nucleinate) the total leucocyte count gave a figure of 2813 per c.mm. and the differential count was as follows:—

Polynuclears	51 %	Eosinophils	0 %
Small lymphocytes ..	16·5 %	Basophils	0 %
Large lymphocytes ..	23·0 %	Myelocytes	6·0 %
Transitionals	3·5 %		

	Class— 1	2	3	4	5
Arneth count	61 %	29 %	7 %	2 %	1 %
Arneth index	93·5 %				

Red cells show early anæmia. Several normoblasts seen.

These results, however, did not appear to coincide with any improvement in the general condition of the patient who rapidly became worse and died on May 28th. *Pentose nucleotide* injections in 10 c.cm. doses had been commenced on the previous day. Unfortunately, it was not possible to carry out a *post-mortem* examination.

We are unable to obtain any evidence in this case of a previous ingestion of amidopyrin as an exciting cause. There was, however, an obvious focal infection of dental origin. It is doubtful if an earlier administration of pentose nucleotide would have affected the ultimate issue of an acute fulminating case such as this, with a total leucocyte count below 1000.

I am indebted to Prof. I. Walker Hall for the blood counts and examination of the films.

RIGHT-SIDED EVENTRATION OF THE DIAPHRAGM

WITH NOTES ON A CASE

By F. G. Nicholas, M.B. Lond., D.M.R.E.
ASSISTANT RADIOLOGIST TO THE MIDDLESEX HOSPITAL, LONDON

AND

A. M. Nussbrecher, M.D., M.R.C.P. Lond.
LATE MEDICAL REGISTRAR AT THE HOSPITAL; PHYSICIAN TO THE SELLY OAK HOSPITAL, BIRMINGHAM

Eventration was first recognised as an entity by Jean Louis Petit (1674–1750). The reports that followed his description were sporadic, but of late years interest in the condition has revived. Writing in 1923 Morison[1] defined it as follows: "It is generally accepted that the term Eventration Diaphragmatica should be applied to those cases of congenital origin in which there is a diffuse relaxation of one-half of the diaphragm, so that it extends high up into the thorax forming a sac. . . ." He himself reporting six left-sided cases stated that all those hitherto recorded, except Eppinger's,[2] have likewise been on the left side. This is not strictly correct, however, because Hamdi[3] published a right-sided case in 1905; the eventration occurred in a man of 50 and contained stomach and liver. There is also a third case described by Bayne-Jones[4] in 1916 in a man of 52. Here the clinical diagnosis was confirmed at operation: the dome of the right side of the diaphragm reached the third rib in front and showed paradoxical movements; the liver was high up in the chest.

Wessler and Jaches[5] mention a case of eventration in which distended coils of colon occupied most of the right side of the chest; at operation the right side of the diaphragm was found intact but atrophied. They state that in right-sided eventration the liver is displaced downwards.

Golob[6] records a case of asymptomatic right-sided eventration discovered on routine examination in a man of 57 suffering from carcinoma of the œsophagus.

Upensky's[7] three cases occurred in women, aged 19, 25, and 31 respectively. They all showed paradoxical movements of the diaphragm. He draws attention to the great difficulty in differentiating right-sided eventration from right-sided diaphragmatic hernia.

Morris's[8] case is interesting because transposition of abdominal viscera was present in addition to right-sided eventration.

The following case, which, for reasons set out below, we regard as one of right-sided eventration, is the ninth recorded.

CASE REPORT

The patient is a woman of 57, single. Nothing of interest in the family history. Very delicate since birth, and in early infancy her life was often despaired of. In 1908 while planting flowers in the garden she experienced a sudden severe pain in the right side of the chest. Thought to have pleurisy and explored with a needle several times, with negative results. Dr. Samuel Gee was called in and pronounced the condition to be one of congenital atelectasis. Patient states that she always has a feeling under right arm "as if something were there" and that she is tender in that spot. Never cyanosed, but always tended to get out of breath on going upstairs. She has been an invalid for several years on account of rheumatoid arthritis. She was recently treated for "depression" at the Woodside Hospital. An abdominal tumour, which eventually turned out to be the liver, was discovered there, and she was transferred to the Middlesex for further investigations.

Appetite good. No abdominal pain. No constipation or diarrhœa. The only evidence of digestive disturbance are slight flatulence and occasional morning vomiting. She complained of cough recently and a slight hæmoptysis occurred seven months ago.

Examination.—Colour fair. No clubbing of fingers. Heart regular; apex-beat in fifth space, in nipple line; soft systolic murmur at apex; second aortic sound accentuated. B.P. 180/110. Diminished movements on the right side of the chest. Tactile fremitus absent at the right base. Lower half of right thorax dull to percussion. No breath sounds heard over dull area, but occasional gurgling is plainly audible, especially after taking liquids by mouth. Above, the breath sounds are poor and a few crepitations are heard, but air entry fair at right apex. Lower edge of liver felt in right iliac fossa. Central nervous system: nil abnormal found. *Joints*: typical changes of rheumatoid arthritis.

RADIOGRAPHIC FINDINGS

Chest.—A dense shadow obscuring the detail of lung and other structures was seen to occupy the middle and lower zones of the right lung. The upper border of the shadow was convex and peaked in one place, suggesting the possibility of an adhesion. The rest of the lung fields appeared clear, and the heart and the mediastinal contents showed no displacement (Fig. 1). The absence of lung markings over the affected part and the lack of mediastinal displacement confirmed the clinical findings of atelectasis of the right middle and lower lobes. In the lateral view (Fig. 2) in the upright position, the left side of the diaphragm was well outlined and normally placed, and the upper border of the shadow noted on the right side in the anterior-posterior view was seen to be dome-shaped and reaching the level of anterior part of the second rib (Fig. 2). The movements of the upper border of the shadow on the right were poor but synchronous with those of the left side of the diaphragm.

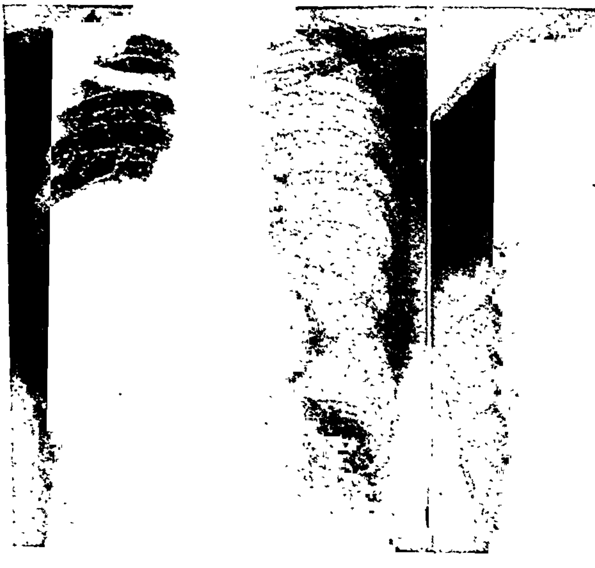

FIG. 1.—A.P. view of chest showing marked elevation of the right side of the diaphragm.

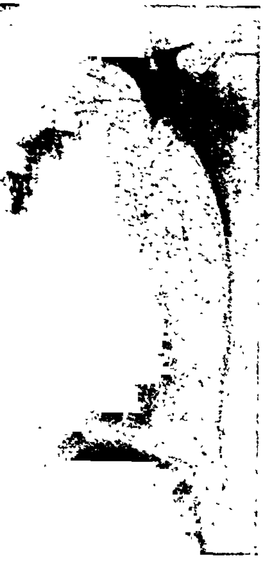

FIG. 2.—A lateral view showing both sides of the diaphragm.

Opaque meal examination.—The œsophagus was normal in length, position, and function. The stomach showed no abnormality apart from its low position and slight dilatation, the lower part of its greater curve being 2 in. below the level of the iliac crest. The duodenal cap was found stretched out, pointing upwards towards the right side of the chest. In the upright position the stomach had great difficulty in expelling the meal through the cap, and barium was seen passing upwards in a very narrow stream making a small loop before entering the right side of the chest. No constricting point was noticed (Fig. 3). In the lying position the stomach emptied with greater ease and coils of small intestine were soon outlined in the right side of the chest. Further passage of the meal demonstrated that not only the small gut, but also the cæcum and most of the colon were in the right thorax.

An opaque enema confirmed the barium meal findings as regards the colon and showed its intra-abdominal part extending obliquely from the right side of the chest to the rectum. The length of the intra-abdominal part of the colon was approximately 12 in. (Fig. 4).

It is interesting to note that despite the abnormal position of most of the gut the examination revealed no gross disturbance of function. The stomach took over five hours to empty, as was to be expected from the extent of its dilatation and the degree of stretching of the duodenum. There was no delay in the passage of the meal through the small intestine and at five hours both the intrathoracic and intra-abdominal parts of the colon were outlined. At 24 hours the small intestine was empty, but at 48 hours a residue of barium was still present throughout the colon.

Position of the other viscera.—The lower border of the *liver* extended to the middle of the sacrum; its upper border could not be traced definitely and only a little of the liver shadow was seen to the left of the spine. A cholecystographic examination showed the *gall-bladder* lying over the middle of the body of the sacrum; it functioned normally. The *spleen* was situated in its normal position under the left cupola of the diaphragm. Both *kidneys* were well outlined after an injection of Uroselectam. The left kidney was slightly low in position, its pelvis being opposite the body of the second lumbar vertebra; the right kidney was high, its pelvis being opposite the body of the twelfth dorsal vertebra, but it was clearly within the abdomen.

DIAGNOSIS

There are many problems in the diagnosis of diaphragmatic abnormalities. Clinical examination alone offers little help, and unaided by X rays would often fail to discover the presence of such lesions; but even X rays may leave the issue unsettled and such methods as inducing a pneumoperitoneum or measuring variations in intragastric pressure may have to be resorted to before a definite diagnosis is arrived at. Our case was fortunately sufficiently clear-cut for us to be able to dispense with these procedures.

The literature is full of conflicting statements as regards movements of the diaphragm in eventration; some authors like Morison[1] affirm that paradoxical movements are always present in the absence of adhesions, others that the diaphragm is motionless, while others again maintain that the movements are synchronous. Our case supports the third contention.

Wood and Wood[9] point out that care must be taken to distinguish congenital eventration from (1) those intra-abdominal conditions where the diaphragm is pushed up, as in ascites, pregnancy, subphrenic abscess, and megalocolon; or (2) such lung conditions as fibroid phthisis, atelectasis, or neoplasm which may cause the diaphragm to be pulled up; or (3) cases of paralysis of the phrenic nerve from disease, trauma, or operation; or (4) temporary elevation due to trauma.

It must be realised, however, that the distinction between congenital eventration and the acquired condition may be exceedingly difficult or even impossible, and that in either case the final state of the diaphragm may be identical—that is, it may present a sheet of thinned and stretched-out fibrous and areolar tissue with few or no muscle-fibres.

In the differential diagnosis of our case we considered: (1) paralysis of the diaphragm, (2) eventration, (3) hernia, and (4) absence of the right half of diaphragm. The negative history, radiographic and clinical findings ruled out the first, and the radiogram showing an unbroken dome of the right sid[illegible] eliminated the third and fourth [illegible] were left with the diagnosis of the rare condition of right-sided eventration and were forced to conclude that it was of congenital origin as we were able to eliminate the other possible causes of high diaphragm.

Our case offers a warning against indiscriminate needling of the chest in obscure cases, because unless eventration or hernia of the diaphragm have been eliminated there is a great danger of perforating a viscus.

TREATMENT

Thoracic surgery has made sufficient advances to tackle successfully many cases of diaphragmatic hernia, but eventration, as far as one can see, is not properly amenable to surgical interference; and even if it were possible in the case here reported, one would still hesitate to advise it since the condition gives rise to

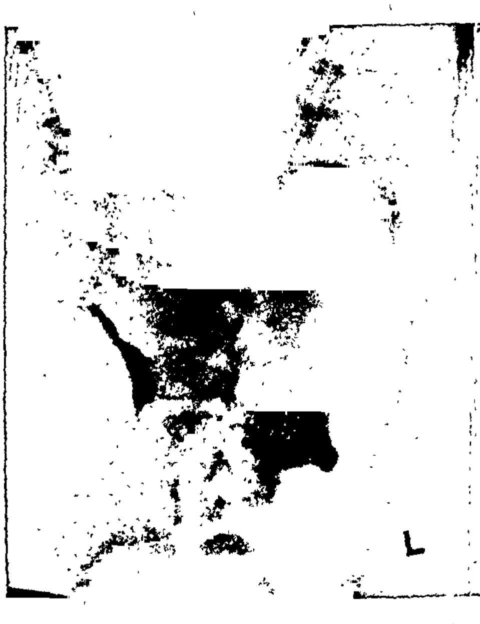

FIG. 3.—This shows the stomach and the stretched-out duodenum; the small intestine is seen in the right side of the thorax.

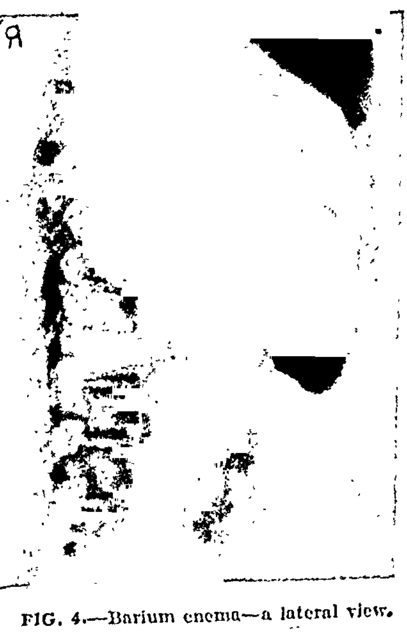

FIG. 4.—Barium enema—a lateral view.

hardly any symptoms and the likelihood of serious disability in the future appears remote.

It is a pleasure to thank Dr. C. E. Lakin and Dr. W. R. Gilmour for their permission to publish this case.

A CASE OF ACETYLSALICYLIC ACID (ASPIRIN) POISONING

BY S. C. DYKE, D.M. Oxon., F.R.C.P. Lond.

CONSULTING PATHOLOGIST, THE ROYAL HOSPITAL, WOLVERHAMPTON

FEW cases of poisoning by acetylsalicylic acid (aspirin) have been reported in this country. Sir William Willcox[1] though including its consideration in a lecture on "toxic drugs," has lately placed upon record the opinion that aspirin is "one of the most valuable and safe of simple remedies." The last case of acetylsalicylic acid poisoning placed on record in this country appears to have been that reported by Hitch[2] in 1928; in this case death occurred after a dose of grs. 1000; in the same year, Jankovich[3] from Paris recorded five fatal cases; he formed the opinion that the fatal dose was in the neighbourhood of grs. 300. More recently, Balázs,[4] writing from Budapest, where the taking of acetylsalicylic acid appears to be a favourite method of attempting suicide, has reported on 752 cases of which, however, only 4 proved fatal. Balâzs considers the minimum fatal dose to be in the neighbourhood of 30 to 40 g. (grs. 450 to 600).

The case here reported ended in recovery; the dose so far as could be ascertained was grs. 435. Inasmuch as on first being seen the patient was in a stuporous condition and quite unable to give any assistance, and as there was nothing in the circumstances of the case to indicate the nature of the trouble it presented a very pretty diagnostic exercise.

CASE RECORD

The patient was a woman, aged 26; she supported herself, and was living in lodgings, both parents being dead; as she was a newcomer to the locality she had no friends or intimates who could give any information likely to throw light on the case.

She was first seen by Dr. D. M. Brown on March 6th, when she complained of buzzing in the ears and nausea; there was no vomiting; temperature 99 and pulse-rate 100. She remained much the same until the evening, when she became deaf and started to wander; she was restless and disoriented all night, and when seen on the morning of March 7th was in a stuporous state with symptoms suggestive of cerebral irritation.

Through the courtesy of Dr. Brown a specimen of urine was made available for examination before the patient was seen by myself. This showed a certain amount of reduction of Fehling's solution, a large amount of acetone, some albumin, and gave a very strong purple colour with aqueous perchloride of iron. Although the amount of acetone present was large, the depth of colour given by the perchloride of iron was much in excess of that met with even in severe ketosis; inquiry at the time elicited the fact that the patient had been given no salicylates by her doctor.

When first seen, the patient was lying with her head buried under the bed clothes; she was unable to answer questions or to speak rationally, and on being disturbed showed resentment and became extremely restless; she was very thin and appeared extremely dehydrated; all reflexes were present and normal; the eye grounds showed no abnormality; Kernig's sign was absent and there was no neck rigidity; temperature was just under 100° F. Respirations were deep and slow and of the type met with in severe "acidosis."

No diagnosis was made; a sample of blood was taken for examination and the removal of the patient to a nursing-home arranged. The blood showed no leucocytosis (white cells 3500 per c.mm.), and films presented no abnormalities; blood-sugar was 0·112 and urea 0·054 per cent.; quantitative examination of the urine showed the reduction to be the equivalent of only 0·35 per cent of glucose. These examinations served to exclude diabetes, uræmia, or an acute bacterial infection as the cause of the trouble, but failed to establish any definite diagnosis.

The immediate indications appeared to be to correct the dehydration and the ketosis, and on admission of the patient to the nursing-home, instructions were given to empty the bowel by enema and to administer 5 per cent. glucose in saline by the rectum and fruit juice and glucose by mouth. The parenteral administration of fluid and glucose was withheld until it could be seen whether the patient would retain fluids administered orally.

Seen in the evening of the same day the condition remained much the same and the diagnosis still in doubt. Lumbar puncture was performed; only a local anæsthetic was used and the patient appeared unconscious of what was going on. The cerebro-spinal fluid was under a pressure of 180 mm. of water; it was allowed to flow until it had fallen to 120 mm. On examination the fluid showed a great deal of acetone to Rothera's test, and gave a strong purple colour with the perchloride of iron; there was no increase of cells or of globulin or albumin, and chlorides were present in normal amount.

The condition improved strikingly after the lumbar puncture; the patient spent a quieter night and in the morning, although semistuporous, appeared better; the hyperpnœa was passing off; she had taken fluids readily throughout the night, there had been no vomiting, and she appeared much less dehydrated. Irregular pyrexia of from 99° to 101° continued. The Rothera reaction of the urine was less deep, but the perchloride of iron reaction remained strong. The urine now also showed bile salts in large amount and a trace of urobilin.

The mental conditon with the pyrexia had given rise to suspicion of some form of infective encephalitis; the normal cytology and the absence of increase in the proteins of the cerebro-spinal fluid served to render this diagnosis unlikely. In the light of the evidence then to hand the case was evidently one of severe metabolic disturbance, due to some poison; diabetes and uræmia had been excluded and no other likelihood of endogenous poisoning presented itself; of exogenous poisons acetylsalicylic acid or some combination of it with a barbiturate appeared possibilities. The cerebro-spinal fluid was tested for the barbiturates with negative results, and a tentative diagnosis of aspirin poisoning was then made.

Lumbar puncture was repeated; the pressure of the fluid was now only 140 mm. It was drained until it fell to 110. The fluid showed a trace of acetone but still gave an intense reaction with perchloride of iron though the colour was less deep than in the previous day's specimen.

On the third day the patient was physically a great deal better; the mental condition remained dull and stuporous and she was still quite unable to talk rationally or to give any account of herself. By this time relatives were on the scene, and with their assistance a search of the patient's room was made; the only relevant article discovered was a bottle which had originally contained 100 5-grain tablets of acetylsalicylic acid, and in which 12 tablets still remained. This was regarded as favouring the diagnosis of acetylsalicylic acid poisoning.

Throughout the first three days of the illness, while mentally dull and stuporous, the patient displayed occasional fits of extreme restlessness especially if disturbed; during these spasms certain movements were regularly repeated; sometimes she raised herself in bed and bringing the hands to within about a foot of the head made movements as though endeavouring to stroke the scalp, but unable to bring the hands any nearer to it; a further series of movements repeated at intervals were identifiable as being associated with certain frequently repeated movements involved in the work by which she earned her livelihood. The condition improved rapidly after the second lumbar puncture, and on the fourth day she was able to hold rational conversation. She complained that her head felt enormously large; this apparently explained the curious stroking movements referred to in the previous paragraph; she further complained of disturbance of vision, stating that everything looked streaked and barred.

An attempt was now made to ascertain from the patient the cause of the trouble; when shown the bottle containing the acetylsalicylic tablets, she at once recognised it as her property and volunteered that she had taken one tablet from it though not for her own use; she inquired where all the missing tablets had gone, and stoutly denied having consciously taken any of them herself. She was unable to account for the missing 87 tablets, and finally admitted that she must herself have taken them. She persisted in her denial of any recollection of having done so.

Inquiry of the relatives elicited a history of peculiar "turns" diagnosed in the past as "petit mal," and it seemed probable that the patient had consumed the tablets while in a somnambulistic state. The patient was seen by myself after this; I am informed by Dr. Brown that she made a good recovery and in about a month was entirely herself again.

COMMENT

Apart from the diagnosis the interest in this case lies in the type of the clinical manifestations; these pointed to a profound disturbance of metabolism, and to toxæmia with a heavy incidence on the higher nervous centres. In the early stages the extreme hyperpnœa was a marked feature; Quincke[5] noted this as one of the symptoms of salicylic acid poisoning; he regarded it as being due to the direct action of the acid radicle of the compound on the respiratory centre and called it "Salizyldyspnœ" Balázs points out that in acetylsalicylic acid poisoning, this hyperpnœa appears only when acetone is present in the urine, and when a state of so-called acidosis has been established. He regards it as being due to the action of the acid substance released as a result of the disturbed metabolism and not directly to the acid radicle of the salicylic acid. He investigated the alkali reserve in several of his patients and found that in extreme cases it might fall to between 30 and 40 per cent. If the hyperpnœa were due to actual liberation of acid radicles from the ingested compound, it might have been supposed that the urine would be strongly acid; in the present case the urinary pH was found to range from 5·8 to 6·4, which is not unduly to the acid side.

Evidence of the widespread nature of the toxæmia was afforded in this case by the urine which showed (in addition to acetone) bile salts, albumin, and granular casts; these findings made it evident that both liver and kidneys were severely damaged. Albumin was present at first in large amount, and at the last observation on the fifth day was still present in traces; bile salts remained present in fair amount throughout the period of observation.

The temperature ranged during the first four days from normal to 101°; it settled on the fifth day; about a week later, I am informed by Dr. Brown, it again rose and remained up for several days; no physical signs indicative of inflammatory trouble accountable for the pyrexia could be found. Balázs noted similar pyrexia in several of his cases; he regards it as being due to a disturbance of the cerebral heat-regulating centre.

Treatment.—Even in the absence of a diagnosis, the obvious indications in this case were from the onset to correct the dehydration, to combat the acidosis, and to support the liver against further damage. To this end, as mentioned above, glucose-containing fluids were pushed in every possible way. The question of the exhibition of insulin was considered but the normal blood-sugar level was regarded as a contra-indication; Balázs found it of no service. As a means of combating the ketosis he recommends the administration of sodium bicarbonate both enterally and parenterally; in my experience, sodium bicarbonate is of little value in combating the ketosis of diabetic coma, and was accordingly not used in this case.

The beneficial effect of lumbar puncture was striking; on both occasions on which it was performed it was followed by a sudden and definite improvement in the general condition. The very strong reaction with ferric chloride given on both occasions by the cerebro-spinal fluid would indicate the presence in it of large amounts of the drug, and it is reasonable to suppose that benefit was due to removal from contact with the central nervous system of fluid saturated with the noxa. The beneficial effect of drainage of the cerebro-spinal fluid in this case of acetylsalicylic acid poisoning is in conformance with general experience in barbiturate poisoning in which also the noxa is taken up in large amount by the fluid.

SUMMARY

A case of poisoning by acetylsalicylic acid is described. The dose was 435 grains; the symptoms were those of profound toxæmia with evidence of hepatic, renal, and cerebral damage; symptoms referable to the alimentary tract were absent; lumbar puncture was beneficial; recovery ensued.

PAPILLŒDEMA CAUSED BY A CERVICAL CORD TUMOUR

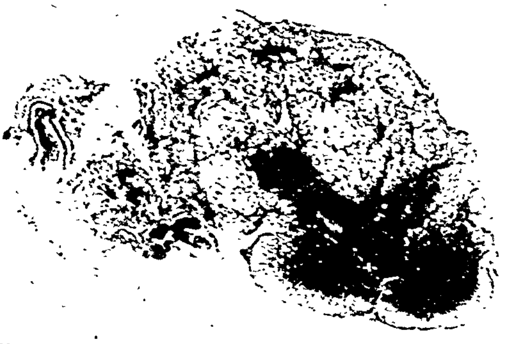
By Douglas McAlpine, M.D. Glasg.,
F.R.C.P. Lond.

PHYSICIAN IN CHARGE DEPARTMENT FOR NERVOUS DISEASES, MIDDLESEX HOSPITAL; PHYSICIAN TO HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE, LONDON

THE occurrence of papillœdema with a tumour of the cervical cord has been so seldom reported that the following case seemed worth recording:—

A woman, aged 20, was admitted to Middlesex Hospital on July 20th, 1934. She said that she had been in good health until June, 1932, when she noticed an aching pain in the left occipital region; soon afterwards the neck became stiff, so that she had difficulty in turning her head to the left or bending it backwards. In December, 1932, she experienced pain in the right shoulder and down the outer side of the right arm; these pains were aggravated by coughing and sneezing. A few months later similar pains were felt in the left arm. In January, 1934, she was admitted to a hospital on the south coast because the pain in the neck had become increasingly severe. During her stay in this hospital she had attacks of nausea without vomiting but accompanied by moderate headache. At no time did she notice any weakness of her arms or her legs. On April 29th, 1934, her neck was manipulated for a supposed torticollis. On coming round from the anæsthetic she noticed that the left leg had become stiff and weak; seven days later the right leg was similarly affected; she also found that the movement of the head was further limited. The pain in the back of the neck became more severe and was accompanied by frontal headache and nausea. Before the manipulation she had experienced slight difficulty in starting micturition but afterwards she had retention followed by incontinence.

Examination.—Mentally the patient was alert and coöperated well. She was unable to lie flat in bed because extension of the head caused pain. The head was constantly flexed to the right, but without any definite rotation. Suboccipital tenderness was noted especially on the left side. Pupils equal and reacted normally. No ptosis. Ocular movements full. Inconstant nystagmus. Approximately 3 D. of papillœdema was present. Corneal reflexes brisk. No sensory loss on face. No facial weakness. No deafness. Remaining cranial nerves normal. *Upper limbs.* No wasting. Power at all joints both arms good. No abnormal posture. Reflexes present and equal with the exception of a diminished left triceps jerk. No cerebellar signs. *Lower limbs.* Total paraplegia: right leg in extension; left leg in mild flexion. Deep reflexes exaggerated. Plantar responses extensor. Strong tendency to involuntary flexor spasm. *Sensation.* Hyperæsthesia on outer aspect of both arms as high as the shoulder. All forms of sensation diminished on inner aspect of both upper arms as far down as the elbow. Postural sense, stereognosis, and compass test normal in both hands. All forms of sensation much diminished on trunk and lower limbs up to the level of D. 2 segment. Complete postural loss of the toes of both feet. Incontinence of urine.



Section of the tumour at the seventh cervical segment.

The patient showed no sign of active tuberculosis in chest, and no enlargement of superficial or of mediastinal glands. The liver and spleen were not enlarged. The cerebro-spinal fluid (lumbar route) had an initial pressure of 100 mm. water, which on jugular compression rose to 140 mm.; the descent was slower than normal. The fluid was yellow with rapid clotting and contained protein 1·78 per cent. Cisternal puncture showed an initial pressure of 305 mm. water, with slightly yellowish fluid containing protein 0·18 per cent. Radiography of skull and spine revealed no abnormality.

Pre-operative diagnosis.—The history suggested a mid-cervical tumour. The highest limit of sensory loss appeared to be at the level of D. 1; but there was hyperæsthesia as high as C. 5. There was no definite evidence, from the history or the signs, of a primary posterior fossa tumour. The clinical picture could be explained by a high cervical tumour of considerable length which had penetrated the foramen magnum and so caused an increase in intracranial pressure. However, one would have expected a tumour in this situation to have caused weakness in the arms. The possibility of two tumours had to be borne in mind, one in the posterior fossa and one in the cervical region. An intramedullary rather than an extramedullary tumour of the cervical cord on the whole seemed the likeliest diagnosis. The patient was transferred to the Hospital for Epilepsy and Paralysis, Maida Vale, and was operated upon by Mr. Charles Donald on August 24th. The laminectomy extended from C. 1 to C. 5, and later the edge of the foramen magnum was also removed. A marked bulging of the dura was apparent which, when opened, showed the cord much enlarged by a tumour which was partially extramedullary and involved the cord itself. The cord was swollen from just below the foramen magnum to beyond the lower limit of the wound. A piece of tumour was removed which proved to be a glioma. Subsequently the papillœdema subsided somewhat. A month after the operation the motor power of the upper limbs was still unimpaired; however, the patient developed bedsores and had attacks of respiratory embarrassment, one of which proved fatal on Oct. 2nd.

Post-mortem.—An elongated tumour was found, partly extramedullary and partly intramedullary, extending from C. 1 segment to approximately D. 1 segment. It lay posteriorly, and chiefly on the right side of the cord. The surface was irregular and soft. Serial sections showed that the tumour was mainly extramedullary at the level of C. 1 to C. 3, and below this level invaded the cord. The intramedullary portion was confined to the dorsal half of the cord. At the level of segments C. 6 to C. 8 it reached its maximum width. No cerebral tumour was found; there was a moderate bilateral hydrocephalus.

DISCUSSION

The association of papillœdema with a cervical tumour is extremely rare. No attempt has been made to make a full search for isolated cases, but Elsberg,[1] in his well-known book on "Tumours of the Spinal Cord," makes no mention of papillœdema in dealing with tumours situated in this region. Elsberg and Strauss [2] in 1929 reported five cases of high cervical tumour, in which the tumour lay both within the vertebral canal and the posterior cranial fossa, and papillœdema was absent in all of them. In each one the tumour was circumscribed and its removal was possible. Carlill and Carling [3] have reported a case very similar to the present one.

A female, aged 41, experienced pain in the left arm followed by weakness in this limb and later weakness and numbness in the legs. Three months after the onset headaches became marked; three dioptres of papillœdema was present on the right side and a hæmorrhage was seen around the left disc. There was atrophy of the intrinsic muscles of both hands, a spastic paraplegia, and a dissociated type of anæsthesia on the trunk and right leg. The cerebro-spinal fluid by the lumbar route showed 0·6 per cent. albumin and by cisternal puncture 0·01 per cent. Lipiodol was held up opposite the fifth cervical spine. A cervical laminectomy disclosed a uniformly enlarged cervical cord that did not pulsate; papillœdema rapidly subsided after the operation. Attacks of unconsciousness, relieved at first by cisternal puncture, followed, but the patient died a month after the operation. Post mortem the tumour was found to extend to the base of the brain. There was moderate internal hydrocephalus.

Davis [4] showed a similar case before the New York Neurological Society in 1923.

A male, aged 24, for two years had suffered from headache, dizziness, and vomiting. Subsequently he improved but showed slight papillœdema, diminution of the deep reflexes in the arms, and a left extensor plantar response. No sensory changes were found. The cerebro-spinal fluid findings were negative but no mention is made of the protein percentage. Two months later he showed weakness and atrophy of the arms and hands and sensory loss between segments C. 3 and D. 1. On one occasion he had a generalised convulsion without loss of consciousness. A mid-cervical laminectomy disclosed a cord completely filling the dural cavity with an apparent lack of fluid below level of segment C. 4. At this level an intramedullary cavity was disclosed. The papillœdema subsided. In this case the tumour was evidently a diffuse *intramedullary tumour of the cervical cord possibly associated with syringomyelia.*

Papillœdema very rarely occurs in syringomyelia. Alpers and Comroe,[5] however, have described such a case in which there was much papillœdema which led to the consideration of a cerebral tumour in addition to the cord condition. A subtemporal decompression was performed but the patient died shortly afterwards. In addition to cervico-dorsal syringomyelia a marked degree of hydrocephalus was present which the authors considered was due to an inflammatory process of the roof of the fourth ventricle extending into the lateral recesses which had probably blocked the foramen of Magendie and Luschka. They referred to other four cases of syringomyelia showing papillœdema; in two of these there was much internal hydrocephalus, the cause of which was not determined. In one case there was a tumour of the fourth ventricle. In the remaining cases only clinical data were available.

The cause of the papillœdema in the present case is not clear. The tumour did not extend into the foramen magnum. The cord was uniformly enlarged and it filled the subdural space at the level of the lower cervical segments. It should be noted that the protein content of the cerebro-spinal fluid, obtained by cisternal puncture, was high. Theoretically a high cervical tumour extending through the foramen magnum into the posterior fossa, or vice versa, might be expected to produce papillœdema more readily than a tumour confined to the cervical cord. Clinically, however, this seldom occurs except possibly in isolated cases. It is probable that with a circumscribed tumour such as is most frequently met with in this situation the block is not complete; on the other hand, a diffuse glioma of the cervical cord leads to a uniform enlargement and the block is greater, even if the tumour does not actually extend into the foramen magnum. It would be unwise to speculate further from such limited material on the actual cause of the papillœdema in these cases. Three points, however, suggest themselves for consideration. Firstly, in each of the three cases referred to the tumour of the cervical cord was a diffuse one; secondly, in two of the cases the maximum growth of the tumour had not occurred at the uppermost level of the cervical cord; thirdly, the tumour tends to fill the whole subdural space at its maximum point of growth.

It has to be borne in mind that cerebral gliomas are occasionally associated with metastases in the spinal cord.[6] The commonest variety of glioma to metastasise in this way is the medulloblastoma, the favourite seat of which is the cerebellum. Confusion might therefore arise between the type of case reported in this paper and a medulloblastoma of the cerebellum with a secondary deposit in the cervical cord. Nystagmus might occur in both conditions. However, in addition to a careful history, which would probably indicate the initial site of the tumour, the medulloblastoma would declare itself by the presence of cerebellar signs.

Another feature of interest in the present case is the absence of paresis in the upper limbs despite the involvement of the whole of the cervical enlargement by tumour. Perhaps this may be explained by the dorsal situation of the tumour, but it is well known that diffuse glioma of other parts of the nervous system, particularly of the brain-stem, may cause remarkably few focal signs.

SUMMARY

1. A case of diffuse glioma of the cervical cord associated with papillœdema is described, and two other similar cases are referred to. Certain deductions are made as to the conditions necessary for this association.

2. The case is also noteworthy because of the retention of motor power in the arms.

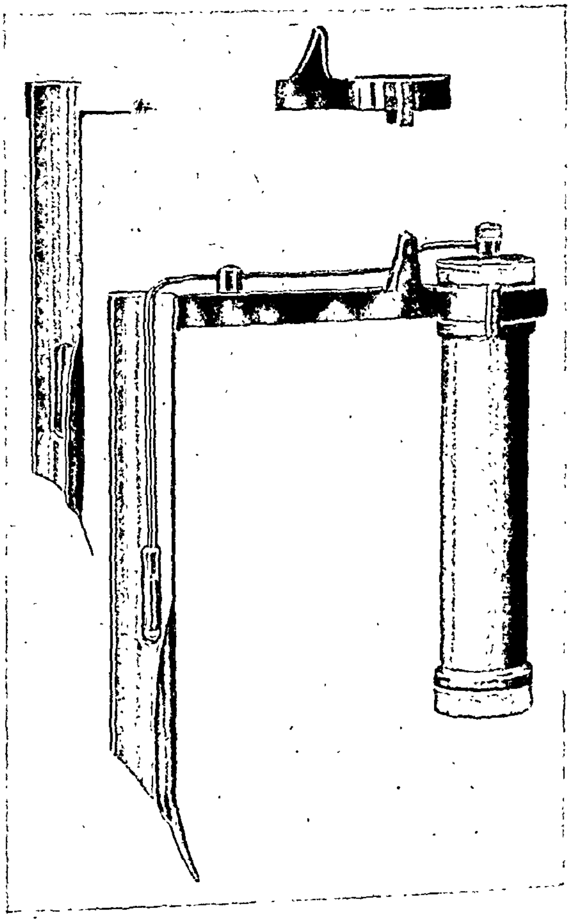
NEW INVENTIONS

A DETACHABLE LARYNGOSCOPE

It has appeared to me undesirable to boil the part of the laryngoscope which contains the electrical equipment so I have had this part made detachable. A smaller mouth-piece is also made which can be fitted on to the handle of the apparatus for use with children. The actual tube of the laryngoscope is made flatter on the upper side so that the tongue is kept more out of the way and it is easier, by means of an introducer, to pick up a tube introduced through the nose and push this through the cords.



The laryngoscope has been made for me by the Dental Manufacturing Company, London.

JOHN ELAM, M.R.C.S.

REVIEWS AND NOTICES OF BOOKS

The Subnormal Mind

By Cyril Burt, Professor of Psychology, University of London. London: Humphrey Milford, Oxford University Press. 1935. Pp. 368. 10*s.* 6*d.*

Whatever comes from the pen of Prof. Burt is assured of scientific detachment and clear exposition. When some years ago he published the "Young Delinquent" he established himself as more than an academic psychologist, as one who could give at once a sympathetic and scientific account of human problems. In this book he maintains the same humanistic spirit; his work in mental tests has always shown a devotion to accuracy in method and deduction. The book is important in that it gives a clear account of the psychology of mental defect and dullness, and of the methods for their assessment and the educational manner of handling them. The chapter on delinquency is a lucid résumé of the author's earlier volume, but the chapters on the neuroses are new in matter and in method of exposition. Dr. Burt clearly distinguishes between asthenic and sthenic neuroses; in the former group he places the exhaustion states usually described as neurasthenia and some anxiety states. The asthenic neuroses are largely physical in origin; whereas sthenic neuroses are mainly psychical. Inasmuch as he is largely concerned with the conditions in children he does not fall back upon the deep layers of the unconscious for explanation. The history is briefer in such child cases and the psychic patterns less complex. While frankly sympathetic towards psycho-analysis, he does not hinder the reader with the more recondite psychoanalytic explanations, although it is to be assumed that he could accept in the main the Freudian psychology. Among the sthenic neuroses he places the hysterical group, compulsions, obsessions, and anger neuroses—in fact, the behaviour disorders. All these conditions call for social handling and psychotherapeusis from encouragement and suggestion to full psycho-analysis. It would be difficult to think of a book in which mental defect and psychoneuroses have been more clearly and accurately described in simple language, and most medical men, including specialists and general physicians, would be the wiser for studying this readable volume.

Annual Review of Biochemistry

Vol. IV. Edited by James Murray Luck, Stanford University. California: Annual Review of Biochemistry Ltd. 1935. Pp. 639. $5.

The appearance of each new volume of this annual review is anxiously awaited by workers in laboratories. This year there are many changes in the personnel of contributors, sometimes, but by no means always, for the better. Some of the articles are of especial interest. The section on Biological Oxidations and Reductions by R. Sonderhoff is excellent, giving a good summary of the present position of this ever-changing subject. The recent investigations of Wieland on the dehydrogenases of yeast are very clearly described, and the work of Szent-Györgyi and others on muscle dehydrogenase is noted. The section closes with a succinct summary of the relationship between Warburg's yellow enzyme and the flavins. Recent work on carbohydrates and glucosides by Sir J. C. Irvine and G. J. Robertson is also summarised, with a good review of the work that has lead to the establishing of formulæ for some of the disaccharides and polysaccharides. The Chemistry and Metabolism of the Compounds of Sulphur by H. B. Lewis is a particularly valuable contribution which will be much appreciated. The section on the hormones by B. A. Houssay is disappointing in that recent developments, particularly with regard to the sex hormones, are not described at all clearly. B. E. Holmes's article on malignant disease is a useful addition to the book, but we would have liked to have seen a fuller discussion of the relationship between certain sex hormones and malignant disease. One of the most interesting sections in the book is Robert Robertson's summary of the present position of knowledge with regard to the chemistry of the alkaloids.

The work as a whole is quite up to the excellent standard of the three previous issues, and is therefore necessary to all biological workers.

Public Ill Health

By C. E. McNally, Hon. Treasurer, Committee Against Malnutrition. London: Victor Gollancz Ltd. 1935. Pp. 224. 5*s.*

This is a provocative book and is intended to provoke. The author is as angry as Jonah was when the Almighty called upon him to denounce Nineveh and afterwards relented. Mr. McNally is exceedingly displeased with Sir George Newman for what he regards as his official tolerance of widespread physical deterioration. Where the truth about the prevalence of malnutrition lies between the late C.M.O.'s apparent optimism and the author's extreme pessimism cannot be determined so long as there is no accepted objective standard. Mr. McNally's chapters are a useful contribution to the study of malnutrition, but he is, we think, under some misconception as to the functions of an officer of the Ministry of Health. Whatever his personal views may be, a civil servant can hardly express criticism of "the whole economic structure of the milk market" or the restriction on the import of foods.

The personal issue apart, there can be no quarrel with the author's main thesis of the association of disease and poverty. Some criticism is possible of certain points: thus the failure of young adult life to respond to the fall in the tuberculosis death-rate is a widespread phenomenon not limited to depressed areas, and is a puzzle to tuberculosis experts, nor is close association proved between maternal mortality and malnutrition, witness the statement in the Scottish report, "Scrutiny fails to reveal that lack of food was a factor in maternal mortality." But that large numbers of our people live under economic and social conditions under which optimum health is difficult or impossible of attainment will not be disputed, and it is well that this should be set forth with a reformer's zeal. The main subject dealt with in this respect is diet. There are useful chapters on food values and requirements, and justifiably caustic comment on the economics which permit the wholesale destruction of food-supplies while populations lack the necessities: there is also sympathetic understanding of the difficulties, too seldom appreciated, which encumber the housewife living in poor property. We have thus on the one hand an insistence on the B.M.A. dietary standard as a minimum, and on the other hand emphasis on the impossibility of attainment of this minimum by a large section of the population. Hence in the author's view ill-nutrition is inevitable.

The problem is not primarily medical but economic.

How his laudable desire that every family should have sufficient purchasing power to obtain more than the B.M.A. minimum is to be fulfilled the author does not indicate: it is unfortunately at present beyond attainment by many wage-earners. There are many counsellors in the market place—communism, social credit, birth control, return to the land, restriction of imports, freedom of trade: there is no certain guide to the promised land and the author does not help us here. Few would, however, dispute that the condition of our people is better than formerly, and even the author admits this as regards school-children, though he qualifies his statement by the words "as reflected by the look of the children." We have travelled far since the Report on the Sanitary Condition of the Labouring Population of Great Britain in 1842, which initiated the public health movement and doubtless will travel further. But progress hitherto made is no ground for complacency, an attitude which this book will help to combat. It is probable that the next orientation of public health will be in the direction of nutrition, with an increasing recognition of its importance and the filtering through to the general population of the scientific knowledge now available. Mr. McNally's book will help to stimulate such a movement.

Theory and Practice of Anæsthesia

By M. D. NOSWORTHY, M.A., M.D., B.Ch. Cantab., Anæsthetist to Westminster Hospital. London: Hutchinson Scientific Publications. 1935. Pp. 223. 12*s.* 6*d.*

THIS is a first-rate book for any man to study when he is beginning to give anæsthetics. That is not to say that it contains no substance for the experienced anæsthetist; indeed, it is so well conceived and clearly written that the expert may gain much from its perusal. Dr. Nosworthy's attitude towards his subject is throughout scientific and up to date, but he is fully alive to the value of the older methods and insists that the student must be thoroughly taught the use of ether and chloroform before he is allowed to extend his experience to other drugs. The author has a high opinion of the value of carbon dioxide in many conditions, especially for producing separation of the vocal cords. He commends cocaine (10 or 20 per cent.) as a spray to the throat to prevent laryngeal reflex, especially before laparotomy, and this measure, which originated we believe with Magill, is certainly not used as often as it deserves to be; its efficacy in aiding abdominal relaxation is remarkable. Dr. Nosworthy does not fail to point out the care that is needed to obviate inhalation of foreign matter when the larynx is thus deprived of its reflex.

In discussing respiratory failure under ether he makes a statement with which we cannot agree. It is fatal, he says, to resort to artificial respiration, as then the patient, from lack of carbon dioxide, will never breathe again on his own. Theoretically this may be right; in our experience it is not true in practice. In discussing the peripheral causes of respiratory arrest Dr. Nosworthy is able to show how some of the most modern methods may cause, if ill-applied, the very trouble they are designed to remove. For spinal analgesia Dr. Nosworthy prefers percaine and stovaine to novocain. His advice on the choice of the appropriate anæsthetic in various conditions, premedication, and after-effects is concise and helpful. An attractive feature of the book is that it contains no superfluous words. The print is of a capital size and clearness, and the illustrations plentiful. We should like the author to reconsider the use of the word "anæsthesia" in the title where "anæsthetics" would be appropriate; the former is a state (of loss of feeling), the latter is an art which may be practised.

Laboratory Manual of Physiological Chemistry

Third edition. By MEYER BODANSKY, Director of Laboratories, John Sealy Hospital, Galveston, and Professor of Pathological Chemistry, University of Texas; and MARION FAY, Associate Professor of Biological Chemistry, School of Medicine, in the University. New York: John Wiley and Sons, Inc.; London: Chapman and Hall Limited. 1935. Pp. 274. 10*s.*

THIS volume constitutes the third edition of a work which is the practical counterpart of Prof. Bodansky's well-known "Introduction to Physiological Chemistry." Both the books have had a success which can be attributed to the clear way in which they are written and the fact that the author has maintained a modern outlook. Of especial interest is the full practical course, which would however be considered too full for English medical students, whose curriculum does not provide much time for biochemistry. Most of the methods are colorimetric, and few teaching laboratories in this country are sufficiently well equipped to supply all the students with colorimeters.

British Journal of Children's Diseases

(Vol. XXXII., July–September.)—In a paper entitled A Contribution to the Epidemiology of Poliomyelitis Dr. Hjalmar Wennerburg, chief physician to the Epidemic Hospital, Gothenburg, maintains that neither the contact theory nor the water theory can solve the problem of infantile paralysis, but that the theory that the disease is disseminated by insects clearly explains all hitherto obscure phases of its appearance. As regards the species of insect, he is inclined to suspect some kind of mosquito.—Dr. E. Ashworth Underwood, in continuation of his article on the Neurological Complications of Varicella, deals with laboratory investigations of the cerebrospinal fluid, the relation between the occurrence of nervous complications, and the type of varicella, which shows that nervous complications are more liable to occur after severe attacks of varicella; the prognosis based on a study of 109 cases, of which 12 died, 80 recovered completely, 15 showed recovery with some sequelæ, and 2 did not recover; the pathology, epidemiology, and theories regarding ætiology. The last are classified in the following five groups: (1) The occurrence of encephalitis following varicella is purely fortuitous. (2) The nervous symptoms are due to the virus of some known disease. (3) The nervous symptoms are due to some unknown virus. (4) The condition is due to the virus of the primary disease, varicella. (5) The anaphylactic theory enunciated by Glanzmann, who holds that the nervous complications following varicella are a local anaphylactic phenomenon due to sensitisation of the nervous system to the actual virus of the disease.—In continuation of his Analysis of Over Four Thousand Cases of Educational Deafness seen during the past Twenty-five Years Mr. Macleod Yearsley describes a method of procedure whereby deafness in children can be detected at an early age, and urges that the deaf child should commence his special education as soon as possible, especially if he is born deaf or has become deaf during the first two years of life.—The abstracts from current literature are devoted to dermatology and syphilis.

THE LANCET

LONDON: SATURDAY, SEPTEMBER 14, 1935

THE USE OF ASPIRIN AND SOD. SAL.

NOT the least of the contributions of chemistry to human well-being is the gift of aspirin, now manufactured and swallowed by the ton. Its analgesic effects and its safety are so widely known that its use has long passed into the control of the general public, with much encouragement from the manufacturers and little guidance from the medical profession. Yet the doctor is asked from time to time whether it is "safe" to go on taking aspirin, and he meets now and then a cautious patient who will venture to take five grains for her headache but is afraid to risk ten. He prescribes both aspirin and sodium salicylate very often himself, but not always with the precision or the understanding of their effects which modern knowledge renders possible. Only very rarely will he meet the clinical picture of poisoning from gross overdosage, so vividly described elsewhere in this issue by Dr. S. C. DYKE, but such cases are on record, and include fatalities not only from accidental or suicidal administrations but also—witness a recent French report[1]—from injudicious therapeutic use.

Decoction of willow-bark was a febrifuge dating from ancient times. Salicylic acid was prepared from it in 1838, and synthetically in 1860. Sodium salicylate was introduced as a remedy for acute rheumatism in the 'seventies, and hailed as a specific. Many regard it as such to-day, but on slender evidence. Since the cause of acute rheumatism is not known, no specific effect on the causal agent is at present demonstrable, and the question can be decided only by considering the amelioration of symptoms. Sodium salicylate reduces the temperature in acute rheumatism, but it does the same in "influenza" and some other febrile states, and to a slight extent in many normal subjects. It relieves pain, both in this and other conditions. Neither of those actions is specific, yet together they constitute most of the salicylate effect in acute rheumatism. The arthritis, it is true, subsides at the same time, which a gonococcal arthritis will not do under salicylate treatment; but then an acute rheumatic arthritis will often subside under antipyretic and analgesic treatment with other drugs, such as quinine and morphia. On the whole, however, the salicylates in acute rheumatism have a more prompt, regular, and satisfactory effect than other drugs or drug combinations and for that reason they remain unquestionably the remedy of choice. Such treatment is mainly if not entirely symptomatic, and unfortunately it does not seem to prevent the development of rheumatic carditis, or to influence the course of rheumatic chorea where antipyretic and analgesic actions are not called for. Where and how salicylate exerts its analgesic effect is unknown. It lowers temperature by disturbing the heat-regulating centre, causing vasodilatation in the skin, increased heat-loss, and often sweating. Larger doses cause ringing in the ears and vomiting, the latter being a central and not a gastric effect. The largest doses produce stupor. So far as is known, the antipyretic action, the vomiting and the coma form a sequence of effects exerted by increasing doses of salicylate on the brain. We choose to call the first therapeutic and the second and third toxic, but they may well be all of the same nature. In rheumatic fever the full therapeutic effect is desired. Sodium salicylate is absorbed and circulates as sodium salicylate; most of it is excreted unchanged in the urine, where it appears inside 10–20 minutes; the remainder is partly destroyed in the body, and elimination is complete in a couple of days. With such rapid absorption and excretion, accumulation is not to be feared, and dosage must be large and frequent if the adequate concentration in the blood is to be reached. Hence it is both safe, and necessary to a full therapeutic effect, to give 10–20 grains of sodium salicylate, hourly or two-hourly, until the patient vomits or his ears ring, which is likely to happen after 120–200 grains have been given. Then it should be stopped, or continued at a lower level, according to the course of the temperature and other clinical features.

Pharmacologically aspirin closely resembles sodium salicylate, but there are certain differences. Although sparingly soluble in water, it is absorbed from the intestine as fast as salicylate, and much of it reaches the blood as sodium acetyl-salicylate, which almost certainly has a more pronounced analgesic action than salicylate. It is rather more slowly excreted, but the same principles as for salicylate apply to its use in acute rheumatism, the "toxic" dose being a little smaller. To the stomach it is slightly irritating, and in an acid stomach some hydrolysis can occur yielding highly irritating salicylic acid. The chief value of the sodium bicarbonate which is customarily given with aspirin, as well as with sodium salicylate, is to counter these effects. With aspirin it will also counter any disturbance of the acid-base equilibrium which that acid—unlike the neutral sodium salicylate—might produce. HANZLIK,[2] to whom we owe much of our quantitative knowledge of the salicyl compounds in medicine, found bicarbonate without effect on the "toxic" symptoms of salicylism, and, although this has been disputed, it is supported by the fact that bicarbonate obviously does not impair the therapeutic effects of salicyl compounds, which are of the same nature as the "toxic" ones. He also found no difference between natural and synthetic salicylates, which used to be set against each other years ago; both of them are equally potent and equally toxic, and with modern methods of manufacture neither is at all likely to contain any harmful impurities. Aspirin has the peculiarity that not a few subjects are sensitive to it in the allergic sense, and after taking it may develop urticaria, œdema of face or pharynx, salivation, or asthma. They usually learn to avoid it, but there is real danger in it for some asthmatics who may not know of their sensitivity, or take it unwittingly in some proprietary form; two cases have recently been reported[3] [4] where 5 grains precipitated fatal asthmatic attacks. Apart from that danger however, aspirin in ordinary doses appears to be singularly safe, without harmful effects even after long periods, and not viciously habit-forming; while such evidence as we have, including Dr. DYKE's case, points to a fatal dose of the order of 500 grains.

THE ROUND WORLD

SHROPSHIRE is a proper place, and the enjoyment of anyone going up and down that delectable county will be about doubled if he reads and digests the guide book which Prof. W. W. WATTS, F.R.S., this year's president of the British Association, published about 15 years ago. It is an exceptionally good book for its purpose, for out of an account of the minutiæ which may be seen he builds up a convincing demonstration that the appearance of a neighbourhood and the lives of its inhabitants are due at bottom to its geological history. In the presidential address to the Association which he gave at Norwich last week he returns to the same theme in its wider aspects and discusses how the surface, not of a county but of the world itself, has come to look as it does. It is a little disconcerting to the layman to learn that there is no explanation generally acceptable to geologists of how the hills and valleys came into existence, no explanation, that is, of the features which, with all respect to those who love the wide skies of East Anglia, make up what most of us call "scenery." Trivial mounds and ridges may be the obvious results of glacial action; minor furrows are equally clearly the handiwork of rivers. These things were realised in the revolution of geological thought which led up to the "Origin of Species"; the wearing away of the earth's surface here and its piling up there have gone on in the past as they go on now, and the ceaseless action of everyday weather is responsible for the variety of surface which charms our holiday moods and, guided by Prof. WATTS, excites our interest. Such was LYELL's great contribution to the progress of knowledge. But when it comes to larger features the matter is not so clear and the origin of the Great Glen or of Snowdonia are matters on which there is still much difference of expert opinion. We used to be told that the skin of the earth has wrinkled as it cooled, as does the rind of a shrivelling orange. But is it possible that this has happened without the intervention of local changes so sudden and so great that they are indistinguishable from the paroxysms and catastrophes which were the universally accepted cause of the surface appearance of the earth till about 100 years ago? We might think more of these if we lived over a less phlegmatic part of the earth's crust and if earthquake had not dropped out of the occasions of violence and sudden death enumerated in our Litany. It is the present belief that the blocks of land which form our continents are floating on a denser liquid mass much as icebergs float in the sea. That they do not move about as fast is plain, but it seems quite likely that they have moved as much, and it is quite certain that what is now land has been under the sea often enough. These changes seem to need some occasional, perhaps periodic, motion of a violent and extravagant kind, and to the question of how that may have come about Prof. WATTS devotes the more technical parts of his address. One comforting reflection emerges—that through all these changes and chances the line of life has never been broken and biological evolution has gone on. We owe indeed much of our knowledge of it to the very fact that sea and land have been turned upside down. And if live things have survived so far, it seems hardly likely that they will succumb to any similar convulsions in the future; there will always be an ark of some kind.

IS CANCER OF THE LUNG INCREASING?

IN spite of the number of papers which have appeared in the last few years on the subject of lung cancer, there is still no decisive evidence whether this form of malignant disease is really on the increase or not. The recorded death-rate in England and Wales has certainly shown a pronounced rise during the last 30 years, but the very magnitude of the increase suggests, as the Registrar-General has pointed out, improved means of diagnosis as at least a major cause. One difficulty of accepting it as the sole cause is that the mortality-rate of males has risen considerably more than that of females. The impossibility of assessing the part played by such changing standards of certification of death has led to the attention of workers being transferred to the statistics of the post-mortem room, where a more stable degree of accuracy is likely to prevail. With these figures we are, however, faced with the problems of selection. Patients admitted to hospital are only a sample of all patients, and those submitted to autopsy are only a sample of all those dying in hospital. Whether persons suffering from intrathoracic cancer are more or less likely to be admitted to hospital to-day than, say, 25 years ago we do not know. In some hospitals it appears probable that they are more easily admitted, for purposes of teaching, ameliorative treatment or research. Where changing proportions of the dead are submitted to autopsy there is, likewise, no means of determining whether the type of case sent to post-mortem has not also changed. For instance, with a growing interest in lung cancer, patients in which this condition is suspected might be more frequently autopsied than in previous years. This would result in an apparently rising incidence. On the other hand, if patients dying of some other causes of death were more frequently than heretofore sent to autopsy we might well observe a declining incidence of lung cancer. This rate—the ratio of lung cancers to other causes of death—is, in fact, dependent both upon the numerator and the denominator of the fraction and changes in either must influence its level and trend.

[3] Lamson, R. W., and Thomas, R.: Jour. Amer. Med. Assoc., 1932, xcix., 107.

[4] Dysart, B. R.: Ibid., 1933, ci., 446.

In a recent paper[1] R. D. PASSEY and J. McD. HOLMES, working with a combined grant from the London Headquarters and the Yorkshire Council of the British Empire Cancer Campaign, suggested that a more satisfactory denominator consists of the number of patients admitted to the wards of the hospitals. It is not unreasonable, they argue, to expect that if there be a large increase in the number of in-patients, there will be also a proportional increase, other things being equal, in the number of patients admitted with lung cancer, which will be reflected in an increase of the latter in the post-mortem room. The incidence-rate they use is, therefore, the number of post-mortem intrathoracic neoplasms expressed as a percentage of the admissions to hospital. Their figures, which were obtained as part of a larger inquiry into the incidence of cancer in general, the results of which are to be published later, were derived from 16 large teaching hospitals of London, the provinces, and Scotland. The statistics for all these hospitals combined show a considerable increase in the absolute number of lung cancers recorded at autopsy. But concurrently there has been between 1894 and 1924 a corresponding rise in the total admissions to hospitals, so that the percentage incidence has shown no significant change over those 30 years. In the last five-year period taken, 1924–28, the percentage incidence has risen, but this change is derived nearly entirely from 5 out of the 16 centres. In these particular centres the authors believe there are associated special circumstances, which they discuss, which may well have contributed to the increase. Generally, therefore, they find by this method no evidence to support the view that the incidence of lung cancer is appreciably on the increase.

These figures, though suggestive, hardly lead to a decisive answer. Over the period studied the total number of patients admitted to these hospitals has risen enormously, and in those hospitals which show no proportional increase in lung cancer this rise in total admissions has been greater than in those that do show some increase in lung cancer. In the former total admissions have risen by nearly 40 per cent. between 1909–13 and 1924–28, in the latter by 23 per cent. It is obvious that this change in the admissions may not equally affect all conditions. If, for the sake of argument, all lung cancers were admitted now and previously but to-day other morbid conditions are admitted which previously would not have been taken in, we should observe a declining proportion of lung cancers. As pointed out above, the denominator of the ratio is just as important as the numerator, and we can by no means be certain that it has not changed differentially. It might be argued that the lack of proportional increase in lung cancers in certain hospitals is due to the relatively greater number of admissions in recent years from other causes. That argument may be fallacious, but the point it places at issue is fundamental to the authors' case.

DECORTICATION OF THE HEART IN PICK'S DISEASE

THE clinical picture of chronic adhesive pericarditis complicating rheumatic heart disease is a familiar one. The diagnosis of adherent pericardium is commonly made when the degree of cardiac hypertrophy seems excessive, when heart failure is early and intractable, or when signs of adhesion between heart and chest wall are evident. In such cases it is assumed that adhesion to the rigid chest wall embarrasses cardiac systole, and surgical measures have been directed to removal of part of the bony wall in order to enable the heart to contract more completely.

There is, however, another and far rarer form of chronic thickening of the pericardium, first described as an entity by FRIEDEL PICK of Prague in 1896, which is inadequately and often incorrectly described in medical text-books, and which hitherto has seldom been recognised during life. Dr. PAUL WHITE of Boston, who came to England this summer to deliver the St. Cyres lecture of the National Hospital for Diseases of the Heart, made this rare form of chronic constrictive pericarditis the subject of his lecture. We are indebted to him for the most complete account of the disease yet published in this country.[1] Pick's disease consists essentially of a chronic thickening and induration of the pericardium, often with calcification. The heart is imprisoned in a rigid cage which prevents diastolic expansion, and soon leads to venous stasis. In contrast to the rheumatic type of chronic pericarditis, Pick's disease causes little or no enlargement of the heart, and murmurs are exceptional. The cardinal features of the disease consist of dyspnœa, œdema, engorgement of the neck veins, enlargement of the liver, and ascites. Abdominal swelling is often an early symptom, and in the absence of any objective sign in the heart may suggest cirrhosis of the liver. For this reason PICK used the term "pseudo-cirrhosis of the liver" in his description. Owing to the frequent occurrence of calcium deposits in the indurated pericardium, which can be detected by X rays, radiological examination of the heart is often of great value in diagnosis. A low blood pressure and a small pulse are also characteristic. The ætiology of Pick's disease is obscure; some cases are undoubtedly tuberculous, and in others there is a history of antecedent acute pericarditis of infective origin, but acute rheumatism apparently plays no part in the ætiology.

The importance of better recognition of Pick's disease lies not in its frequency, but in the discovery of its amenability to treatment. Because the myocardium and the valves are not primarily involved, and are often relatively healthy, the cardiac function can be restored by removing the constricting pericardial cage. White describes the operation employed to this end by Dr. E. D. Churchill at the Massachusetts General Hospital, which consists essentially of resecting as much as possible of the indurated pericardium. Those who were privileged to see White's remarkable film of the operation in progress are not likely to underestimate the magnitude or dangers of the surgical procedure involved. It is not one to be lightly undertaken, and calls for an experienced thoracic surgeon. The results of successful decortication of the heart in this way are however impressive. White records 12 cases; of ten cases operated on by one surgeon, six were completely cured and one much relieved. His lecture should stimulate the interest of physicians in the diagnosis of Pick's disease and encourage thoracic surgeons to study Churchill's work.

ANNOTATIONS

THE MATRIMONIAL CLINIC

A METROPOLITAN police-court magistrate offers to members of the medical profession a new, if limited, opportunity of social service. In his recent book, "Wife *v.* Husband in the Courts,"[1] Mr. Claud Mullins explains that, in a proportion of matrimonial disputes in the police-courts, the good offices of a doctor are essential. Where sexual relations are the cause of the discord, Mr. Mullins believes it to be the only helpful course that the parties should be persuaded to discuss their troubles with a doctor before they embark on litigation against one another. Religious or moral appeal, he declares, will do little good. Constructive re-education in decent sexual standards is what is needed, and this task, he maintains, should not be assigned to laymen. He stipulates, however, that the doctors must be carefully selected; "unfortunately some of them have inhibitions and cannot help in cases of sexual difficulty." Lest the medical profession takes this reproach too much to heart, it may be added that elsewhere Mr. Mullins is equally critical of magistrates. A justice, he says, who has an excess of false modesty had better devote his or her attention to motoring summonses and avoid matrimonial cases. On the other hand he is aware of justices at the opposite extreme who, to quote his own words, find a sadistic pleasure in earing about other people's sexual experiences or o belong to the school that finds sex at the base all human actions. These too he recommends to absent themselves when husband and wife come to court.

Mr. Mullins's writings have shown him to be a reformer. His latest book sets out clearly the improvements he proposes. Some of them, commended in his final chapter, have already been passed into law with surprising promptness in the recent Money Payments (Justices' Procedure) Act. Others, which require no statutory authority, he has introduced in the south-western district of London where he himself sits. He has set aside, for instance, a special afternoon each week for matrimonial cases; in this way they are no longer mixed up with ordinary criminal business. He does his best to exclude the public and the newspaper reporters. Gossiping neighbours, he says, make trouble by repeating what they hear; and once a domestic story gets into the papers all chance of reconciliation may be lost. He knows how legal formalities and conventions perplex common folk. The police-court plan of putting one person in the dock and another in the witness-box may work well for a charge of burglary but is inconvenient for a matrimonial dispute. Mr. Mullins puts husband and wife on chairs facing him at an angle. They give their evidence comfortably from where they sit, instead of being marched about the room. They are encouraged to talk at their ease and are not pressed to cross-examine one another—a task of which the law optimistically believes all parties capable. By such devices the police-court becomes something like a matrimonial clinic. The magistrate of the old school confined himself to administering the law as he had received it, giving the applicants their remedy if the case was made out. The magistrate of the new school asks the probation officer to have a chat with the parties before the summons is heard. The old school conscientiously decided the relevant questions—Has desertion been proved? Has the husband wilfully neglected to maintain his wife? The new school postpones the answer to these questions till preliminary inquiry has exhausted the possibilities of healing the breach; it refuses to treat the summons as a declaration of war and the hearing as a dog-fight. It is in this scheme of informal investigation that Mr. Mullins seeks to enlist the doctor for "moral ambulance" work.

There is of course one obvious difficulty. The doctor will be told things which the magistrate would ordinarily never hear. Mr. Mullins appreciates that doctors will not receive confidences unless they keep secrets. At his own police-court, he says, professional confidence is respected and neither the magistrate nor the probation officer seeks to infringe it. In this work of informal preliminary investigation, by whomsoever it be undertaken, there is also a legal obstacle. The magistrate's decision must be based upon evidence given in open court; the private reports of an investigator, and the personal opinions he forms as to the rights and wrongs of the case, are not evidence. Mr. Mullins admits that the existing law prevents him from taking into account what the probation officer tells him in this way. An exception has been made for juvenile courts; special statutory rules allow the magistrate to receive and consider written reports furnished by probation officers without their being read aloud. The introduction of similar procedure for matrimonial cases is probably a long way off. Public opinion will hardly be persuaded of the propriety of inquisitions, however well-meaning, into English home life, and native caution will hardly encourage semi-official intervention between husband and wife. If meanwhile the progressively minded magistrate feels that his social work is thereby hampered, the doctor will be relieved to find that, if he has been able to help towards the sympathetic adjustment of domestic discords, he will not be expected subsequently to divulge the confidences entrusted to him.

OLIVE OIL LAVAGE IN CARBOLIC ACID POISONING

DISSATISFACTION with existing antidotes to acute phenol poisoning has prompted L. Goodman and A. J. Geiger[1] to an attempt to find a commonly available oil which will be more effective than liquid paraffin whose efficacy they regard as negligible. In their view alcohol also is disappointing as an antidote and may even do harm. Their search was limited to the true oils because of the readiness with which these oils are miscible with phenol, and of these olive oil appeared to be the most suitable because it is bland, cheap, and a household commodity. The minimum lethal dose (M.L.D.) of phenol was standardised on rats at 0·3 g. of phenol liquefactum per kg. of rat, and the protective value of various substances was then assessed against a dosage of one or two M.L.D. The first 45 experiments showed liquid paraffin administration to be ineffective, and subsequent experiments were devoted to studying the effects of olive oil, which was found greatly to raise the survival-rate of their rats if administered *before* the phenol. Administered *after* the phenol its value was not nearly so great unless it was used as the medium for gastric lavage.

Unfortunately they do not report any control experiments of lavage with plain water; in the absence of these, the criticism arises that the real reason for the benefit obtained with olive oil gastric lavage may have been the mechanical removal of the poison and that many other fluid media might have worked equally well. Most people with experience in the treatment of cases of acute poisoning hold that removal of the poison by thorough and painstaking washing out of the stomach is of far more importance than the administration of antidotes. Lavage properly performed entails the use of many pints of fluid. Goodman and Geiger have not tried olive oil in human cases. There seems no reason why it should not be tried as the fluid used in gastric lavage for carbolic acid poisoning, but there is no evidence to justify its use merely as a neutralising antidote without lavage.

THE WAYS OF THE LOCUST

IN a recent address to medical officers of health,[2] Dr. Dunstan Brewer urged his hearers to go to the locust and consider her ways; for there is a suggestive analogy between the appearance of plagues of locusts and of infectious diseases, and there is the possibility that the excessive multiplication of the locust that precedes migration is associated with insusceptibility to a natural agent which normally keeps the numbers down. The locust (as an economic problem) is very much in the air at the present time, and it is to be hoped that the laws which govern the devastating migrations of this insect will before long be understood. This much seems to be established. During the years in which locust swarms are absent, the insect is living a solitary life in certain "permanent habitats" under an outward form so different from its swarming cousin that it was long regarded as another species. Then something happens—it is generally believed to be a particular combination of favourable climatic conditions—and the locust population begins to increase. When this increase has reached a given level the insects tend to congregate, and in the course of a few generations (a generation takes about six weeks) they become transformed into a swarming phase which differs in form and coloration from the solitary phase of the same species as markedly as it does in temperament. Indeed there is some experimental evidence to prove that it is the restless activity of the densely crowded swarms which is directly responsible for their striking differences in form and colour. Once the migrating swarms are formed they are faced by legions of enemies. They are preyed upon by birds and mammals, attacked by insect parasites, subject perhaps to epidemic bacterial diseases, and assaulted by the traps, the dusts, and the poisons of locust officers. Ultimately these factors, combined maybe with a destruction of their own food-supply, gain the upper hand. The numbers decrease, the swarms are thinned out, and gradually the species reverts to its peace-loving solitary phase.

PERCAINE FOR SPINAL ANALGESIA

MOST anæsthetists who have persevered with the trial of the method of using percaine which was introduced by the late Dr. Howard Jones have come to regard it as extremely valuable. In the *Journal of the Canadian Medical Association* for August, Dr. F. Tempe records the result of 800 injections. He does not use the method on any patient with a blood pressure below 110 systolic, and he employs no preliminary injection except half a grain of ephedrine, a quarter of an hour before operation, in order to counteract the "hypotensive crisis of the twentieth minute, the result of the diminution of the vascular tone through paralysis of the sympathetic vasoconstrictors." Dr. Tempe refers to another precaution which is too often omitted. This is the immersion of the ampoules in warm water so that the solution is at body temperature when introduced into the spinal canal. It is highly probable that this device greatly reduces the likelihood of meningeal irritation. The amount of percaine which he uses does not exceed 15 c.cm. even for operations on stomach, biliary passages, or kidney. He finds that the 15 minutes' wait commonly recommended after injection can generally be curtailed, but he regards as a danger signal any complaint of headache or nausea in the first five minutes. The article includes other useful little tips of practice, and it is obvious that the success which Dr. Tempe has enjoyed is the reward of a careful as well as highly intelligent employment of a method excellent in itself but easily misused.

AN UNSUSPECTED OCCUPATIONAL HAZARD

ACCOUNTS come from two independent sources of an occupational risk previously unsuspected. It may arise in the process of electro-welding or in using oxy-acetylene burners, when, in either case, work is being carried on in a confined and badly ventilated space. Careful research at the Harvard School of Public Health[1] has revealed that during these processes nitrous fumes are generated from combination of the atmospheric gases. Hence arises an insidious and far more serious hazard than that of metal fume fever with which it has been confused, the confusion having arisen from the fact that sometimes galvanised surfaces are being treated by the welding flame when zinc oxide is boiled off. Metal fume fever, also known as brassfounders' ague, does no lasting harm; its effects are not cumulative; and the substances causing it, such as the oxides of zinc and magnesium, are not true industrial poisons. The inhalation of nitrous fumes is different; the risk is insidious, as the fumes can be breathed without much immediate inconvenience; but a few hours later pulmonary œdema supervenes and not infrequently ends fatally. Such was the fate of animals exposed sufficiently to the fumes from electro-welding. A fatality is reported from America of a man employed in the basement of an apartment house at electro-welding the two halves of a galvanised hot-water tank. In this country no less than 17 other cases, one being fatal, are reported[2] following the use of large oxy-acetylene burners for the purpose of heating a heavy steel crosshead in order to remove it from the rudder post in a confined space on board a large liner. Here then is a hazard which, when once its existence and nature are recognised, may easily be avoided. Either the workplace may be well ventilated, or the fumes may be removed by local exhaust, or suitable respirators or air masks may be worn.

CAUSATION AND TREATMENT OF MORPHINE ADDICTION

A NOVEL theory of morphine addiction and of the symptoms which may attend the withdrawal of the drug has been advanced by Dr. Iwan I. Ostromislensky, of New York, formerly professor of organic chemistry in the University of Nijni-Novgorod. His theory of addiction propounded is based on analogy with anaphylaxis. Morphine, it is suggested, generates an antigen and the antigen produces an antibody which appears on about the twentieth day after daily administration. The withdrawal of morphine from an addict, on this assumption, will leave the antigen to react on its antibody and occasion symptoms of anaphylactic shock, accompanied by a "craving" for the drug, which if unrelieved may result in collapse and death. This theory of addiction has led Dr. Ostromislensky to advocate the employment of a new synthetic preparation (diphenylmethylpyrazolonyl) as a "valuable therapeutic for the unfortunate morphine addicts." It is claimed that the new remedy, which has been named "rossium," relieves the craving, checks the withdrawal symptoms, and overcomes addiction to the drug. In a communication to the Russian Medical Society in New York[3] it is stated that the remedy is being tested in hospitals and sanatoria in the United States and in Canada.

MARRIAGE OF SYPHILITICS UNDER TREATMENT

ONE of the urgent questions put to their doctors by adult male patients suffering from syphilis is when intercourse is to be allowed. The conservative practitioner usually allows marriage without restrictions after a period of three to five years of treatment and observation. When the biological urge is very great intercourse is usually permitted after a shorter period to men with negative Wassermann reactions provided that they are actually receiving arsenical injections at the time and that they wear a condom as a protection against seminal infection. That this latter may occur has been shown not only experimentally in monkeys but also by demonstrating spirochætes in human semen by the dark-ground method. In a recent investigation[4] the infectivity was tested of the semen of 25 syphilitic patients, 5 acute and 20 chronic, all under treatment with arsenic or bismuth or both. The semen was collected aseptically and was injected into the testicles of two rabbits within half an hour of ejaculation. After three months of negative observation by dark-ground illumination of puncture fluid taken from the testicles of the rabbits, their inguinal glands were ground up and passaged into two fresh animals, who were similarly observed. In no case was there any demonstrable lesion or spirochætes. The authors draw the conclusion that the syphilitic is not infectious for so long a period as is generally thought, and that marriage might safely be allowed at an earlier period. This conclusion seems to us unwarrantable, being based on 25 cases in which only one examination was made, and that presumably whilst the case was under treatment. Once intercourse is allowed it is unlikely that the average patient will confine himself to specified periods—i.e., during courses of injection—and there is nothing in the experiment to show how long the semen remains safe. D. Nabarro in this country has shown cases where the birth of normal children, conceived after the parents have had some treatment, was followed by the birth of a syphilitic child as the result of a relapse of the disease, or the awakening of a latent syphilis. It would therefore seem wiser to continue to insist on fully three years of treatment and observation before allowing marriage. Greenbaum and his collaborators suggest that their method of examining semen might be of value as a method of testing syphilitic men who insist on marriage before they have had adequate therapy. The test would certainly be a useful adjunct to venereal practice if it proved to be reliable after the first animal inoculation, and the passage into the second animal, which adds another three months to its duration, could be dispensed with; further trial would be essential before this could be assumed, and even then the cautious physician would insist on at least two negative results.

VITAMIN C AND ASCORBIC ACID

OUR leading article of August 24th touched only briefly on the identification of vitamin C with ascorbic acid, and the account given by Mr. S. S. Zilva, D.Sc., in the August *Archives for Disease in Childhood* deserves a further note. The discovery is one which illustrates the intimate relations of chemistry and medicine. Briefly it arose out of two apparently unconnected observations; one the isolation from the adrenal cortex (in 1928, by Szent-Györgyi working in Gowland Hopkins's laboratory) of a strongly reducing hexose derivative, called by him hexuronic acid; the other the elaboration of a test by the late J. Tillmans of Strasbourg to discriminate between lemon juice made from fresh lemons and spurious imitations thereof. Tillmans's test consisted in using 2:6 dichloroindophenol as an indicator, this being decolorised by the real, but unaffected by the artificial, lemon juice; and he came to the conclusion that the substance which reduced the indicator was vitamin C. Hexuronic acid was also found to decolorise 2:6 dichloroindophenol; Tillmans suggested that it was probably identical with vitamin C; and in 1932 Szent-Györgyi actually proved that it had antiscorbutic powers. Then came a series of investigations in the chemistry department of the University of Birmingham by W. N. Haworth, E. L. Hirst, and others, with the following results: (1) the hexose derivative obtained by Szent-Györgyi was found by Haworth and Szent-Györgyi to contain a molecule of water less than is required for a hexuronic acid, and the name ascorbic acid was suggested in its stead; (2) the structural formula of ascorbic acid was elaborated; (3) in conjunction with Zilva the antiscorbutic power of ascorbic acid was shown to be a property of the acid and not of any associated impurity; and finally, (4) *l*-ascorbic acid was synthesised from *l*-sorbose. The synthesis of *l*-ascorbic acid was also carried out and published earlier in the same month by T. Reichstein of Zurich, but his method is not so simple as Haworth's which also has the advantage of being quite inexpensive. L. G. Parsons and P. Schultzer in 1933 reported the cure of scurvy with ascorbic acid obtained from natural sources,[1] and A. D. C. Bell, Parsons, and others have since proved the antiscorbutic powers of synthetic products.[2]

RHODA ERDMANN

THE death was announced last week in Berlin of Prof. Rhoda Erdmann—well known as one of the pioneer workers in tissue culture. Prof. Erdmann began her scientific career as a protistologist. Just before the outbreak of the war she went to America and worked at Princeton and Yale; her interest was aroused in tissue culture, which became her life work. On returning to Germany she was appointed head of the department of experimental cytology of the University Institute for Cancer Research in Berlin, and later was elected professor in the medical faculty of the university. From her laboratory there emerged numerous valuable contributions to the study of growth in vitro, with special reference to malignant growth. In 1922 she published a book entitled "Praktikum der Gewebepflege oder Explantation besonders der Gewebezüchtung," which outlined in detail a complete course of instruction in tissue culture for university students. Prof. Erdmann was perhaps best known to biologists as the founder and editor of the *Archiv für experimentelle Zellforschung besonders Gewebezüchtung (Explantation)*, which under her able direction became the recognised international medium for the publication of researches in tissue culture. She took the leading part in organising the International Congress for Experimental Cytology, and was present in this country at the third meeting of this congress at Cambridge in 1933. At that time her health was the cause of anxiety to her many friends, who admired the courage and enthusiasm which have sustained her in her work during recent years in the face of many difficulties.

IMMUNISATION AGAINST TETANUS

PASSIVE immunisation of the wounded during the war had an immediate and striking effect in lessening the incidence of tetanus. For every 20 cases before, only one occurred after this method was in general use, and those that did occur were mainly mild and chronic. In spite of its comparative success, passive immunisation has certain disadvantages which were pointed out in a letter addressed to our columns[3] two years ago by Mr. H. H. Brown. Of these the chief are: (1) that antitoxin may not always be available, (2) that horse-serum sensitises to foreign protein, and (3) that its protection may pass off too soon. To these should be added another: that tetanus may follow slight wounds for which antitoxin would probably not be given. Active immunisation is free from these drawbacks and Mr. Brown pointed out that there is no adequate reason why it should not be generally employed to protect against tetanus as it is against diphtheria and scarlet fever. For some time past this method has been used officially in the French army, antitoxin being given with the first injection of toxoid, followed by two further injections of toxoid alone at intervals of two or three weeks, when any sort of wound has been inflicted. Mr. Brown would extend its use and suggests the active immunisation against tetanus of all soldiers before they are called out on active service, especially in countries where tetanus is prevalent.

In a recent paper[4] Dr. P. A. T. Sneath and Mr. E. J. Kerslake, working at the Connaught Laboratories, Toronto, have studied the persistence of antitoxin after active immunisation. Serum was obtained from 13 persons two years after the last of a series of three injections of tetanus toxoid. These observers found that the residual antitoxin showed no sign of having fallen below the level found from 12 to 15 months after the last dose (between 0·025 and 0·1 unit per c.cm. of serum). Further, when a secondary stimulus of 1 c.cm. of toxoid was given to these patients it effected a definite increase of titre within a week, and this persisted at significantly high levels after one month. In 12 patients treated in this way, within a week of the last injection of toxoid, five showed 5 or more units per c.cm., two showed 2·5 units, three at least 1 unit, one between 0·1 and 0·5 unit, and one 0·01 unit per c.cm. of serum. The amount of antitoxin so produced fell slightly in some after another month, but persisted at significantly high levels. Titres similarly attained in another group of patients were shown to persist at or above the level of 0·1 unit per c.cm. in nine out of ten patients. The level of 0·1 c.cm. to 0·25 unit per c.cm. of serum represents the maximum antitoxin level reached in the blood-serum of patients injected with 1500 American units of antitoxin.

These observations lend support to Mr. Brown's contention that active immunisation against tetanus for soldiers before they are called out on active service may prove more efficient than the passive method hitherto employed.

"PROGNOSIS"

THE first 66 articles of the series on Prognosis now appearing in our columns have been collected in book form, following the practice adopted for the earlier series on "Modern Technique in Treatment" and "Clinical Interpretation of Aids to Diagnosis." In the volumes previously issued the articles were printed in the order in which they had appeared in THE LANCET; in the volume on prognosis, which is published this week, they have been classified into systematic groups to facilitate quick reference. These groups serve also to suggest gaps which will be filled, so far as is possible, as the series proceeds.

Dr. John Ryle, physician to Guy's Hospital, has been appointed regius professor of physic in the University of Cambridge in succession to Sir Walter Langdon-Brown, who is retiring on Sept. 30th on completion of his term of office. Since King Henry VIII. founded the chair in 1540 all the regius professors except one have held medical degrees gained at Cambridge. The exception was John Blyth, the first regius, who took his M.D. at Ferrara. The twenty-first regius is a London graduate and the first Guy's physician to be thus honoured. To find a younger regius we should have to go back more than a hundred years.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXVIII.—PROGNOSIS IN FIBROIDS

THE extended scope of myomectomy which has been developed during the last two decades has brought with it a considerable increase in our knowledge of fibroids. It would appear that in most cases the tumours as "seedlings" are laid down somewhere between the twenty-fifth and thirty-fifth years of the woman's life, and that after that period further formation of seedlings is uncommon. Fibroid forming is therefore to be regarded as a phase in the life-history of the uterus rather than a habit, and in this respect fibroids are analogous to gall-stones, the formation of which is also a phase rather than a habit. This is fortunate, otherwise the operations of cholecystotomy and myomectomy would be inadequate, for new stones or new fibroids would begin to be formed very shortly after the respective operations, whereas the recurrence of stones after cholecystotomy only takes place in 7 per cent. of the cases, and recurrence of fibroids after myomectomy in only 5 per cent. of the cases.

AGE AS A FACTOR IN PROGNOSIS

Though the ten years from 25 to 35 can be looked upon as the "normal" period during which fibroids may begin to form, there are certain patients in whom they begin earlier, and certain others in whom they begin later.

The growth of a fibroid is at first slow, but as it enlarges the rate tends to increase. It is probable, however, that a fibroid does not commonly give rise to any symptoms or gross signs until five years or more have elapsed from its incipience. The chief exceptions to this rule apply to submucous fibroids, which, by reason of their position, may early give rise to menorrhagia. It is generally assumed that fibroids grow faster the younger the woman, but rapid growth is often observed in the relatively aged.

Relation of age to rapidity of growth.—It is excessively rare for fibroids to be discovered in a woman below 20 years of age, and I personally have never seen them under 19, though their presence in children has been recorded. From 20 to 25 they are still rare, but from 25 to 30 they are met with much more often, though they are still comparatively uncommon. The bulk of patients presenting themselves for the first time with fibroids are between 35 and 50 years of age. When fibroids are discovered in a patient under 25 an abnormal fibroid-forming tendency on the part of the uterus must be inferred.

We have no knowledge as to why some fibroids grow slowly and some relatively quickly. It is generally held that the more vascular the uterus the faster will a fibroid grow, and the effect of pregnancy is cited as a proof of this. It is however doubtful, to my mind, whether pregnancy does have this effect. Certainly much of the enlargement is merely apparent, being due to the hypertrophy of the uterine wall over the tumour. It is, further, a remarkable fact that high vascularity of the uterine wall is usually associated with degenerative changes in the fibroid or fibroids which it encloses. These degenerative changes are necrobiotic in character, the unstriped muscle-fibres of the tumour undergoing a hyaline swelling and softening which may end in complete diffluence, and pari passu with this change large irregular blood sinuses make their appearance in the substance of the tumour. As a result the tumour enlarges, but the enlargement is due to swelling of the fibres and influx of blood, and not to growth in the strict sense of the word. It appears to be an absolute rule that fibroids never form de novo after the menopause, and an almost absolute rule that they do not continue to grow after that event, or even enlarge from causes other than growth, for (excluding malignant transformation) such a happening is limited to the rare occurrence of cystic degeneration. Uterine tumours appearing after the menopause are practically always due to some form of malignant disease, and should be so diagnosed, no matter how much their consistence and shape suggest fibroids.

As far, then, as the rate of growth is concerned, age is an important factor in prognosis only when the patient has passed her menopause, for before this event there is no certain relation between rate of growth and age. It is obvious that the younger the patient the longer time is there for the tumour to grow: a tumour the size of a golf-ball discovered in a woman of 50 is unlikely to attain any great size, simply because, short of unusually rapid growth, there is not time enough before the menopause for it to do so, but a tumour of the same size discovered in a young woman of 30 is practically certain to become large because it has 20 to 25 years in which to grow. In this connexion, it is to be remembered that fibroids postpone the menopause, and patients possessing them most frequently do not experience it until well after their fiftieth year.

Effect of size on symptoms.—Speaking generally, the larger the tumour the greater the likelihood that it will produce symptoms, if it is not already producing them. On the other hand, small tumours may produce marked symptoms and very large ones practically none at all. Some of the largest that the surgeon has to deal with have been thus symptomless for years, so that time has been given them to attain a remarkable size. This particularly applies to broad-ligament fibroids, a variety which has yielded by far the greatest proportion of the giant fibroids weighing anything up to 50 lb. that can be found recorded in the literature.

FACTORS INFLUENCING PRODUCTION OF SYMPTOMS

The prognosis of fibroids, in so far as the likelihood of their producing symptoms is concerned, is largely governed by the age of the patient: the younger the woman the greater the likelihood. There are other points, however, to be considered. The commonest symptom is menorrhagia, and its occurrence is the more likely the more the tumour approaches the cavity of the uterus—that is to say, when the fibroid is submucous. A submucous fibroid causes symmetrical enlargement of the uterus, and hence when this is present the probability of menorrhagia developing (if it has not already done so) is greater than when the uterus presents bosses and irregularities indicating a subserous location. On the other hand, fibroids are more commonly multiple than solitary, so that the undoubted presence of subserous tumours does not exclude the possibility of the uterus containing a submucous tumour. Further, subserous tumours when large quite commonly cause menorrhagia because they increase the general vascularity of the organ.

Menorrhagia, once established, almost always gets worse with time, and the menopause-delaying effect of fibroids is important in this connexion. Patients bled white by the long continuance of excessive periods sometimes state that they lose less than they used to do. They do, because they have so little blood to lose, but when considered in relation to their anæmia the periods are just as excessive or more excessive than ever. It is noteworthy that so soon as the blood content is increased by the administration of liver and iron the amount lost is increased. The attempt to augment these patients' blood content is like trying to fill a bottle with a hole in it. Symptoms due to pressure are most likely to develop quickly when the tumour is growing low down in the uterus, especially when it is situated in the supravaginal cervix. Frequent urination is the common symptom, and later on attacks of retention. Tumours outside the pelvis do not give rise to pressure symptoms until they have attained a great size and sometimes not even then. Degenerative changes may give rise to acute symptoms, but it is impossible to gauge the likelihood of such a happening in any individual case of fibroids, as our knowledge of the cause of these degenerations is insufficient; all that is certainly known being that pregnancy conduces to such changes very markedly, and particularly to that form of necrobiosis to which the adjective "red" is applied. Fibroids are less likely to degenerate after the menopause, but calcareous degeneration is common in old women and can give rise to symptoms. Torsion of a fibroid is a rare event and could only affect one that was subperitoneal and pedunculated.

RELATION OF FIBROIDS TO CHILDBEARING

The prognosis of fibroids as regards childbearing can be approached from two angles: the effect of the tumours on childbearing and the effect of childbearing on the tumours. Speaking generally, fibroids militate against pregnancy, and the more so the more deeply they are placed. Their effect on labour depends on their situation. Small superficial tumours do not interfere with the event, but large, deeply placed tumours may bring about miscarriage or distort the lie of the child, or cause actual obstruction.

Pregnancy has an adverse effect on fibroids chiefly because it induces acute degeneration in them. The question whether it increases their rate of growth has already been dealt with, but whether it does or does not, the united bulk of the tumour and the pregnancy makes the uterus abnormally large. In any case of fibroids the possibility of pregnancy is a strong indication for the removal of the tumour before the event.

CHANCES OF MALIGNANCY

In any discussion on the prognosis of fibroids the chances of malignancy are an important part of the consideration. There are three possibilities: (1) a tumour deemed to be a fibroid may, in fact, be a malignant growth; (2) a fibroid may undergo sarcomatous change; and (3) a carcinoma may develop in a myomatous uterus.

As regards (1), it is to be remembered that it is only in a proportion of fibroids that the medical man can be absolutely certain of the nature of the mass he feels, and that other enlargements of the uterus and certain enlargements of the ovaries or tubes can very exactly simulate the contour and consistence of fibroids. This particularly applies to malignant disease of the ovaries occurring in elderly women, and this is frequently mistaken for fibroids. "Fibroids" first declaring themselves after the menopause are rarely fibroids.

(2) Sarcomatous change is said to occur in 2 per cent. of all cases of fibroids that come to operation, but in my experience this estimate is too high. It is an uncommon event, and such samples as I have seen have mostly been in women who have been known to have fibroids for years but who have been advised against or declined an operation. The advent of malignancy is insidious, being only accompanied by vague pain and discomfort in the pelvis. In most of the cases there has been no suspicion of gravity before the operation, and the microscopical findings have come as a surprise. The outlook is bad, for recurrence after removal is common.

(3) I have no doubt that fibroids predispose to carcinoma of the body of the uterus, for so many of the patients I have operated on for the latter condition have been found to have them. Moreover, corporeal carcinoma is very rare in women before the climacteric; but, in almost all the examples I have had experience of, the malignant growth was associated with fibroids. Carcinoma of the cervix is a rare complication of fibroids because the latter make for sterility, whilst the former is almost limited to parous women.

TYPE OF OPERATION

Finally, we must consider the prognosis of fibroids in relation to operative removal. Of the three operations, myomectomy, subtotal hysterectomy, and total hysterectomy, the operative case-mortality of myomectomy and subtotal hysterectomy is about the same (1 per cent.), whereas that of total hysterectomy is somewhat higher. These figures, of course, apply only to surgeons expert in this class of work. Total hysterectomy removes all possibility of further fibroids, but a few cases are on record in which after the subtotal operation a fibroid appeared in the conserved cervix. It is a most unusual event.

My own figures show that after myomectomy fresh tumours form in the conserved uterus in less than 5 per cent. of the cases, and to the extent of requiring further operation only in less than 3 per cent. The liability is greatest when myomectomy is carried out on young patients, particularly when the uterus contains a number of tumours, for in such persons, as I have already pointed out, a special predilection must be inferred. For example, I once removed 92 fibroids from the uterus of a girl of 19, but within a few years the uterus had to be removed on account of fresh tumours. On the other hand, it is in young women that preservation of the uterus is peculiarly desirable.

CHILDBEARING FOLLOWING MYOMECTOMY

The childbearing value of the conserved organ is considerable, as the following shows:

Out of 77 women on whom I performed myomectomy and who subsequent to the operation desired to have children and were in a position to have them, no less than 30 had conceived by the time I collected these figures. Of these 30 women 26 had conceived once, 2 had conceived twice, and 2 had conceived three times. The manner of delivery was as follows: of the 26 who had conceived once 18 delivered themselves naturally, 6 had Cæsarean section, and 2 miscarried. Of the 2 who had conceived twice, the deliveries were all natural; whilst of the 2 who had conceived three times the deliveries in one case were all natural, while the other had one natural delivery and two Cæsarean sections. The frequency of Cæsarean section is accounted for by the fact that, many of the patients being elderly, it was specially important to obtain a living child.

In conclusion, the following case is worth recording as showing the possibilities of childbearing after myomectomy even in extreme cases. In 1922 I removed seventeen fibroids from the uterus of a nullipara of 27 who was very anxious to have a child. Seven years afterwards I operated again on account of menorrhagia and abdominal pain. Six new fibroids were removed, and in addition "chocolate cysts" were enucleated from both ovaries. In 1934 pertinacity was rewarded, for she became pregnant, and this year I delivered her of a living child by Cæsarean section.

MALIGNANT DISEASE IN THE NATIVES OF KENYA

BY F. W. VINT, M.D., B.Sc.

(*From the Medical Research Laboratory, Kenya*)

THE following observations may be useful as a contribution to our knowledge of cancer in races living in a primitive environment.

In 2378 tissues from the natives of Kenya, examined for all conditions, I have found 546 (or 23·8 per cent.) with malignant change. The tumours found are given in Table I., and the data assume greater importance for native races in general if they are considered in conjunction with those of Smith and Elmes[1] for the natives of Nigeria, quoted in the right-hand column.

TABLE I.—*Analysis of the Tumours Found* (546)

Type.	No. and per cent.	Smith and Elmes[1] Nigeria percentage.
Carcinomata*	277 (50·7)	48·6
Sarcomata†	178 (34·4)	36·0
Melanomata	59 (10·8)	8·0
Endotheliomata ..	15 (2·7)	3·4
Teratoblastomata ..	14 (2·5)	0·4
Chorion epitheliomata .	2 (0·3)	0·2
Hypernephromata ..	1 (0·1)	—

* Including 10 mixed tumours of the parotid.
† Including myeloid sarcoma.

The most striking features of this Table are :—

(*a*) The close agreement between the figures for the natives of Nigeria and those of Kenya.

(*b*) The high ratio of sarcomatous to carcinomatous growths—namely, 2 : 3. The International Year Book (1929)[2] shows that the combined returns for England and Wales, Scotland, and Northern Ireland give a ratio of sarcomata to carcinomata of 1 : 17. In these figures for Europeans no mention is made whether or not melanomata are included with the sarcomata. If one combines these two types of tumours in the native the ratio becomes 1 : 1·6.

(*c*) The large number of melanomata seen in the African. Malignant melanomata in the African have been discussed in a recent paper by Sequeira and myself,[3] and require no further amplification here.

TABLE II.—*Types of Carcinoma* (277)

Type.	No. and per cent.
Glandular	141 (50·9)
Squamous celled	134 (48·4)
Basal celled	2 (0·7)

The types of carcinomata seen are given in Table II. and the distribution of the growths in Table III. In each case the percentage given is the percentage of the carcinomatous growths and not of the total malignant tumours.

TABLE III.—*Site-incidence of Carcinoma* (277)

Site.	No. and per cent.	Site.	No. and per cent.
Limbs (skin) ..	64 (23·1)	Pancreas ..	6 (2·1)
Liver, primary ..	38 (13·7)	Trunk (skin) ..	6 (2·1)
Glands (lymph) ..	29 (10·4)	Stomach	5 (1·8)
Breast	25 (9·0)	Liver (secondary)*	4 (1·4)
Lip, mouth, and palate	17 (6·1)	Abdominal cavity*	4 (1·4)
Face and head ..	15 (5·4)	Larynx, kidney, œsophagus, rectum, thyroid, bladder (each)	2 (0·7)
Genitalia male ..	15 (5·4)	Unspecified ..	14 (5·0)
Genitalia female	13 (4·6)		
Parotid gland ..	10 (3·6)		

* Site of primary growth not stated.

The types of sarcomata are given in Table IV. and the site-incidence in Table V.

TABLE IV.—*Types of Sarcoma* (178)

Type.	No. and per cent.	Type.	No. and per cent.
Round-celled sarcoma	64 (35·9)	Osteosarcoma ..	10 (5·6)
Spindle-celled sarcoma	58 (32·5)	Chondrosarcoma .	3 (1·6)
Mixed-celled sarcoma	24 (13·4)	Myxosarcoma ..	3 (1·6)
Myeloid sarcoma .	14 (7·8)	Liposarcoma ..	1 (0·5)
		Oat-celled sarcoma (mediastinum) .	1 (0·5)

TABLE V.—*Site-incidence of Sarcoma* (177)

Site.	No. and per cent.	Site.	No. and per cent.
Limbs	65 (36·5)	Breast, kidney, liver (each) ..	4 (2·2)
Glands	14 (7·8)	Eye	3 (1·7)
Mouth and jaw ..	14 (7·8)	Intestines ..	2 (1·1)
Bone (unspecified)	8 (4·6)	Uterus, vulva, spleen, lung, mediastinum (each)	1 (0·6)
Ribs and chest wall	8 (4·6)	Unspecified ..	20 (11·2)
Face and head ..	7 (3·9)		
Testicle	7 (3·9)		
Neck	7 (3·9)		
Retroperitoneal ..	5 (2·8)		

EPITHELIOMATA

From the figures given in Tables II. and III. it appears that malignant growths of the skin are of the utmost importance in the East African native. Among the glandular carcinomata 4 cases were diagnosed as tumours of the sweat glands; these taken in conjunction with 2 rodent ulcers, 59 melanomata, and 134 epitheliomata show that cancer of the covering membranes accounted for 36·4 per cent. of the malignant growths found. It is significant that although epithelial tumours are so common in the African, yet basal-celled cancer, so common amongst the white races, has only been diagnosed twice in 546 tumours. Smith and Elmes in Nigeria found 7 in 500 tumours. Yet rodent ulcers are often seen in the white population in East Africa.

The large number of squamous-celled cancers is due to the prevalence of malignant changes in chronic tropical ulcers of the leg, 73 of the epitheliomata being associated with this condition. In an attempt to investigate tropical ulcers from a histological viewpoint, a routine series of examinations was carried out. Through the courtesy of Dr. Procter and Dr. Hargreaves, of the Kenya Medical Service, 282 ulcers excised in a native reserve hospital were obtained. These were an unselected routine series removed from both sexes of all ages, the doctors concerned considering that excision followed by skin-grafting offered the best hope of a cure within reasonable time in general hospital work. In these 282 ulcers were found 1 melanoma almost devoid of pigment, 5 epitheliomata, and 3 cases in a definite precancerous condition. Thus excluding the precancerous conditions 2 per cent. of a routine series of chronic tropical ulcers were found to be malignant. The Annual Medical Report, 1932, for Kenya Colony [4] shows that among in-patients and out-patients treated at the Government native hospitals over 18,000 were seen in one year.

While examining the ulcers one was impressed with the aberrant overgrowth of the marginal epithelium. This was so striking that it is doubtful if any two observers would agree on the number showing precancerous changes. Two main factors appeared to be involved in limiting the atypical overgrowth: (*a*) the dense bed of well-developed fibrous tissue forming the base of the ulcer; and (*b*) fibrosis of the blood-vessels in the ulcer.

During the investigation it was found that 11 per cent. of the ulcers showed foreign bodies or foreign body giant cells. This must be regarded as a high incidence, for only two pieces of tissue were blocked and sectioned from each ulcer and the ulcers varied in size up to 6 or 7 inches in diameter. The foreign bodies were a clear, hyaline, structureless-looking material, and in one ulcer portions of an unidentified worm were found.

BREAST AND GENITAL ORGANS

Malignant disease of the *breast* is not uncommon in the East African native, 25 carcinomata and 4 sarcomatous growths being seen, a percentage of 5·3 of the malignant tumours. Of these, 5 carcinomata and 2 sarcomata were from males. Among the female cases there were 2 cases of epitheliomata and 1 case of Paget's disease of the nipple.

Male genital organs.—The 15 cases seen included 9 cases of epitheliomata of the penis. These were all derived from uncircumcised natives. Circumcision is practised by most of the tribes in Kenya, the operation being performed about the age of fifteen years. Wolbarst [5] states that the morbidity-rate of penile cancer in the United States is at least 2 per cent. and possibly 3 per cent. of all cancer in the male and draws attention to the rarity of the condition in the circumcised. In Kenya where epithelioma is the common form of cancer no case of this disease of the penis was found in a circumcised native.

Among the tumours of the *female genital organs* only 1 case of carcinoma of the body of the uterus was found. One case of sarcoma of the uterus was also seen. Smith and Elmes in their series only had 2 cases of cancer of the uterus and 1 myosarcoma. Thus in 502 cases of carcinomata from Africans only 3 were uterine growths. As in other organs, epitheliomata accounted for the majority of the growths of the female genitalia.

TUMOURS OF THE LIVER

Cazanove [6] states that in French West Africa cancer of the liver is commoner than cancer of any other organ. Snijders and Straub [7] found the same condition of affairs in Javanese coolies working in Sumatra. Strachan,[8] discussing autopsy findings among the Bantu races in South Africa, found the liver to be the commonest site of primary carcinoma accounting for no fewer than 37 out of 73 epithelial tumours. Smith and Elmes had 32 in their series. In the East African 13 per cent. of the epithelial tumours were of primary hepatic origin. The high incidence of this type of growth is best illustrated by autopsy records. In 1100 consecutive post-mortem examinations, the great majority of which were on patients thirty-five years or under, 24 malignant growths were found. Of these, 16 were epithelial and included 8 primary carcinomata of the liver.

Of the 37 cases seen, microscopical examination showed that 31 were liver-celled growths and the remaining 7 bile-duct in origin. The outstanding feature of the livers in which there were growths was the cirrhosis present, usually of a hob-nailed variety. This point has been noted by the various authorities quoted in this article. The relationship between cirrhosis and primary carcinoma cannot be considered a casual one, and it would appear doubtful that the cirrhosis is secondary to the new growth. In a previous paper I pointed out [9] that 67 in 100 livers, removed at consecutive post-mortem examinations from patients of all ages, showed cirrhosis of one form or another. In addition, 16 of the 100 livers exhibited fatty degeneration. Thus in considering cancer of the liver in the East African native it must be borne in mind that one is dealing with an organ extensively diseased before the onset of any malignant changes.

Of the 8 carcinomata seen on the post-mortem table none showed metastases in other organs, the growths being confined to the liver itself.

TUMOURS OF THE INTESTINES

As can be seen from Table III. malignant disease of the intestinal tract is not common. Two cases of carcinomata of the rectum have been seen and 2 of secondary nodules in the abdominal cavity, which from their histological appearances may have been derived from an adenocarcinoma of the rectum. In these 2 latter cases the site of the primary growth was not stated.

Cancer of the stomach, like gastric ulcer, appears to be rare in the East African. In the 1100 autopsies to which reference has been made only 2 cases of gastric ulcer were seen and 1 case of a healed duodenal ulcer.

GENERAL

The tumours examined have been received from native hospitals throughout Kenya and are representative of the native population as a whole. They cannot, however, be taken as statistics for the incidence of cancer. The tumours seen in the Medical Research Laboratory, Nairobi, represent only a small proportion of the tumours found throughout the Colony, and presumably the medical officers in the native reserves see only a proportion of the sick in their district. This will be appreciated when it is understood that a medical officer may have under his charge a district of 3000 square miles and a population of 300,000, and for assistance a few indifferent native dressers.

No mention has been made of the age-incidence of malignant disease in the native. Such records as one possesses are useless, since no registration of births or deaths is carried out in the native reserves and it is impossible to obtain accurate ages from the natives themselves; the figures we have represent an estimate by the medical attendant. However, personal experience and the consensus of opinion of the medical officers from whom inquiries have been made seems to show that the onset of cancer is at an earlier age in the native than in the European, the maximum age-group being 30–40 years. This may be a factor in the high ratio of sarcomatous to carcinomatous growths.

The natives in the reserves in Kenya have been touched only lightly by civilisation. They live under conditions of filth and squalor. Sanitation is almost non-existent as yet and the main food is maize meal. Meat is eaten when available, but this is rarely, since cattle are regarded as currency.

CONCLUSIONS

These observations provide further evidence against the theory that cancer is rare among indigenous peoples living under natural and primitive conditions. As yet only a negligible proportion of the population of Kenya live under "civilised" conditions; but analysis shows that malignant disease is far from rare among them. The distribution in the body differs materially, however, from the distribution recorded in the European.

MEDICINE AND THE LAW

Diabetes Treatment by Unqualified Practitioner

AT a Camberwell inquest last week, where death was found to have been due to diabetes, the South London coroner described the treatment as "arrant rubbish" and the unqualified practitioner who had administered it as a "quack." Sir Bernard Spilsbury gave evidence that the medicine prescribed by this practitioner would have no appreciable effect; it was simply useless. The coroner explained to the jury that, had there been evidence that the treatment had shortened life, a verdict of manslaughter would have been proper. As there was no such evidence (the medicine having no more effect than so much water), a verdict of death from natural causes was returned.

The deceased, a woman aged 32, had suffered from diabetes for several years. She had originally been treated by a duly qualified doctor; he was called in again shortly before her death when she was in a state of coma and a death certificate was likely to be required. The unqualified practitioner who treated her had a plate outside his "surgery" in Peckham Rye which bore the words "Dr. William Mellor, Osteopath, U.S.A., Homœopath, India." He told the coroner that he had obtained a degree in osteopathy at the First National University, Washington, New Jersey, and was an associate of the Western University, Kapurthala, India. "Would you be surprised to hear," inquired the coroner, "that there is no such place as the Western University, Kapurthala, but merely a place which issues diplomas on payment of a fee?" Mr. Mellor replied that the information would surprise him; he had not studied in India but had sat for the examination in homœopathy in London "under the Indian Education Scheme." He explained that he called himself a doctor because of his doctorate of osteopathy; he did not practise as a physician and was not a surgeon or a general practitioner; he held a degree as doctor of medicine from the American Academy of Medicine and Surgery, Washington, but did not practise; he was also a member of the British Homœopathic Association. The coroner, in summing up to the jury, disposed somewhat summarily of Mr. Mellor's titles and qualifications. "He calls himself a doctor of osteopathy but none of the institutions to which he referred are known in the academic world as genuine places where degrees are properly given; in other words he is simply a quack." It is evident, however, that the descriptions which Mr. Mellor had adopted were found impressive by members of the public. A sister of the deceased said that Mr. Mellor had been recommended by neighbours who thought he was a qualified doctor. The preamble to the Medical Act declares the expediency of the public being able to distinguish between the qualified and the unqualified practitioner. Mr. Mellor's plate obscured the distinction.

A Bogus Major of the R.A.M.C.

The police disclosed a curious career of imposture when Richard Gerald Willoughby pleaded guilty at Andover last week to summonses charging him with having unlawfully worn a major's uniform and military decorations at South Tidworth on August 3rd. Willoughby attended a cricket match at the R.A.M.C. ground, driving up in a large car. He was dressed as a major of the R.A.M.C. and wore field boots, a sword, the Military Cross, and other war medals. After watching the cricket he asked to be directed to the officers' mess, where, while accepting refreshment, he told an officer that he had come down from Millbank in connexion with an outbreak of diphtheria. He also said that there was a lot of tonsillitis about. He was afterwards entertained at dinner at the O.T.C. camp officers' mess; here he took too much to drink and was sent back to the military hospital. Doubts having arisen about his identity, he was taken to the police station where he said he was a doctor and a retired major, but could not now call himself a doctor as his name had been struck off the Register. Research by the police failed to show that Willoughby had ever held a commission in the R.A.M.C. The records showed that he had enlisted in the Duke of Cornwall's Light Infantry in September, 1914, as Percy Seymour Kelly, changing his name to Willoughby by deed poll on obtaining a commission in the Royal Fusiliers a month later. He resigned next year, re-enlisted as Robert Kelly and soon obtained a temporary commission as Eric Patrick Cosmo Gordon O'Kelly, but was removed from the Army a few months later. Enlisting again in the Royal Dublin Fusiliers, he deserted in November, 1915. He served once more as Percy Seymour Kelly from July to October, 1918, when he was discharged as physically unfit.

He had posed in London hotels as an officer in the Canadian Rifles. He had travelled round the country as a clergyman, visiting real clergymen, and on one occasion actually preaching a sermon. He served six months' imprisonment in America for impersonating a British officer, and had been imprisoned in Canada for posing as a doctor. He had obtained a situation as a chartered accountant at £1000 a year. He had described himself as Dr.

Robert Beatey Martin in Panama, and had obtained an appointment in that name as ship's surgeon in a British liner. He was landed at Singapore with malaria and, as Dr. Martin, escorted to England a judge who was ill. In 1932 he was sentenced at the Old Bailey to two years' imprisonment for false pretences and indecent assault. It was a remarkable history of fraud, and the Andover magistrates awarded him three months' imprisonment and £5 fine for his escapade at South Tidworth last month.

Puerperal Melancholia and Criminal Responsibility

Newspaper paragraphs last week described proposals for reforming the law of infanticide. Women who kill their babies while suffering from melancholia following childbirth should, it was suggested, be tried by a committee of alienists and psychiatrists instead of by an ordinary criminal jury. The proposals envisage the mother's mental state as partly an economic and political problem. It is hinted that the increase in infanticide may be due to unemployment, the mother being naturally worried at the extra addition to the family when the father is out of work.

Opposition may be expected from the judges, the legal profession, and the Home Office. It will be pointed out that two post-war statutes have operated, and were intended to operate, against mothers being found guilty of murdering their new-born children. The Infanticide Act of 1922 and the Infant Life (Preservation) Act of 1929 enable the most lenient view to be taken. The reformers seem scarcely to have given Parliament credit for the change in the law whereby the disturbed mental state of a mother within a short period after childbirth is now taken specially into account. Those concerned with the administration of justice are jealous of handing over the duties of courts to lay tribunals: they are sure to demand that facts shall continue to be found by magistrates and juries under a system which does not preclude the assistance of expert witnesses. Everyone will be sympathetic towards the anxieties of the mother at childbirth, but there may be some difference of opinion about the alleged increase in infanticide. The latest criminal statistics (those for 1933) suggest that the number of persons annually tried for infanticide under the 1922 Act is falling rather than rising. There was one case under the 1929 Act in 1931; there were no cases in 1932 or 1933. The coroners' statistics for 1933 show that 336 inquests were held on the bodies of newly born children. These were cases where inquests were adjourned under Section 20 of the Coroners (Amendment) Act, 1926, and not resumed, prosecutions being conducted in the ordinary criminal courts. Out of the 336 cases there were 13 verdicts of wilful murder, 2 of manslaughter, and 3 of infanticide. There is nothing to show the relation of these figures either to puerperal melancholia or to unemployment. It is a point with which the official editor of the criminal statistics might deal in next year's volume.

Inquest on Prehistoric Man

The *Times* of Sept. 5th recorded the holding of an inquest in Ireland upon human remains found at Mullaghneish mountain, near Londonderry, and estimated to be over 3000 years old. The evidence indicated that the remains were those of an Irish chieftain of the Bronze Age. They consisted of a portion of a rib, a tooth, and skull bone; they had been roughly cremated and were found in a bowl-shaped urn buried in a vault-like structure of stone in a bog; a substance of the nature of clay within the urn was apparently food to sustain the departed spirit on its journey. The coroner had taken the view that there was a question of ownership. The urn and remains had been removed to the Belfast Museum and he had served a warrant on the curator for their return; he thought the police should have the custody till the ownership was established. An English coroner would probably have left the question of ownership to another court; this was not treasure trove. The coroner's concern is with a dead body, and there are ancient legal difficulties about property in a corpse. The discovery of these ancient remains recalls the fact that there has occasionally been a pious practice of reinterring Stone Age, Bronze Age, or Iron Age skeletons in churchyards and cemeteries. Where piety has thought it necessary to "give Christian burial" to pre-Christian relics, it has been a necessity that must have made strange bed-fellows. It seems almost as incongruous to assert a coroner's jurisdiction over the prehistoric dust upon the shelves of a museum.

BRITISH ASSOCIATION

FOR THE ADVANCEMENT OF SCIENCE

Chemotherapy of Malaria

OPENING the discussion by the chemistry section of the Association on the chemotherapy of malaria, Colonel S. P. JAMES, F.R.S., referred to the distressing effects of the malaria epidemic and famine in Ceylon. The area affected was not as large as Yorkshire, but the cost of relief measures was about £350,000, and during the six months from November to April 14½ tons of quinine, costing £50,700, was used. About £20,000 was also spent on Atebrin. The epidemic had reminded the world once again that no royal road or short cut to the prevention of malaria had yet been found; during recent years similar reminders had come from British India, Malaya, East and South Africa, Nigeria, the Sudan, Mauritius, Trinidad, Barbados, and other British territories overseas. In view of these and other examples it had to be admitted that, despite some remarkable discoveries, existing knowledge on the prevention of malaria was not sufficient. Direct war on the malaria-carrying mosquito was too difficult and too costly for general use, and quinine had failed to maintain its old reputation as the sovereign remedy which meets all needs. More knowledge was needed in many different directions, one of them being the much neglected subject of chemotherapy. Quinine satisfied the practising physician because it promptly stopped most clinical malarial attacks; but it had the grave defects of not preventing infection of either the human host or the mosquito and of not preventing relapses. To discover and prepare drugs which would be effective where quinine failed was the chief aim and object of antimalarial chemotherapy. In Germany two synthetic antimalarials, Plasmoquine and Atebrin, which to a considerable extent fulfilled that requirement, had already been discovered, and now it was to be hoped that England would make adequate arrangements to pursue the subject in the same intensive way and with the same objects in view. Up to the present, said Colonel James, the chemical industries of this country had not concerned themselves with the matter, and the Government grants which had been allotted during the last few years to assist antimalarial chemotherapeutic research had amounted to less than a two-hundredth part of the Empire's annual bill for quinine.

Colonel James then elaborated, with examples, the defects of quinine and the directions in which quinine therapy could be supplemented by atebrin and plasmoquine. It was clear, he said, that the discoveries made by Prof. W. Schulemann and his colleagues at Elberfeld had placed in our hands new antimalarial weapons of great power and precision, but there was still ample scope for further research in this and other countries.

Prof. **SCHULEMANN** then addressed the section on methods of chemotherapeutic research as exemplified by the antimalarial drugs. The successful production of these drugs at Elberfeld had, he remarked, been largely the result of the invention by biologists of new methods of testing the antimalarial properties of synthesised substances. There had been a growth of sympathetic understanding between chemist and biologist with the proper blend of intuition and organisation, and this had spelled progress which could never have been reached by trial and error or purely empirical methods. Plasmoquine, he said, was the thirty-fifth in a certain series to be tried out, and since 1924 only one other effective antimalarial substance had been found. While the operation of these antimalarial weapons was still obscure he surmised that the explanation might be found in the chemistry of surfaces; it had been found that mice could be killed if given drugs on an empty stomach, when they suffered no ill-effects from the same drugs given after a meal.

Prof. **ROBERT ROBINSON**, F.R.S., followed with an outline of the methods employed for the synthesis of potential antimalarials by himself and his colleagues, and discussed some of the results from the point of view of the relation between constitution and antimalarial action. He also directed attention to the pressing need for coöperation between chemists and biologists in a national institute for research in chemotherapy.

Dr. **P. TATE** (for Prof. **D. KEILIN**, F.R.S.) and Dr. **M. VINCENT** then submitted a joint communication on the chemotherapy of bird malaria and its importance in relation to the therapeutics of human malaria. They pointed out that bird malaria was a valuable means of testing the antimalarial action of new synthetic compounds, since many of these act in a similar way in human and in bird malaria. Routine tests on birds are made on asexual stages of the parasite transmitted by direct blood inoculation, but by utilising mosquito infections it is possible to determine the action of a compound on gametocytes and on sporozoites. The results of work on bird malaria are not always applicable to human malaria, but so far every synthetic compound of value in human malaria had been discovered by means of preliminary tests on bird malaria.

Dr. **T. A. HENRY** spoke on antimalarial drugs of natural origin. He said that from natural drugs having a local reputation as remedies for malaria—e.g., the alstonias of Australia, India, West Africa, and the Pacific Islands—a group of alkaloids had been isolated which might be antipyretic but were devoid of antimalarial activity. In order to determine the relative activities of the various cinchona alkaloids, the eight principal alkaloids had been prepared in a pure state and from tests in bird malaria had been arranged in the following descending order of activity: (1) hydroquinine, (2) quinine, (3) hydroquinidine, (4) cinchonidine and quinidine, (5) cinchonine, hydrocinchonine, and hydrocinchonidine. In general it could be stated that any change which diminishes the basic character of such an alkaloid as quinine reduces its antimalarial activity, though it may result in the development of pharmacological activity of another kind.

Sir **RICKARD CHRISTOPHERS**, F.R.S., then read a paper on chemotherapeutic effect as a combination through a basic side chain. He said that a usual conception of chemotherapeutic effect was molecular fit. The chemical nature of such fit was often not very clear, but the necessity of a basic side chain for linkage to protein was sometimes referred to. All antimalarial drugs natural and synthetic had such side chains. With a view to studying such combination, observations had been made upon absorption by red cells of some simple acids and bases, using critical hæmolysis of a given quantity of red cell substance and electrometric determination of the pH as guides to the reaction. It was found that lysis of the cell was brought about through formation of a critical amount of "protein salt," which amount was the same for all acids. With this is associated a fraction due to "hydrolysis" of the salt, which is greater the weaker the acid. This necessitates a larger dose in the case of some acids than others. This "hæmolytic dose" can be calculated with considerable approach to experimental findings. "Hæmolysis" is associated with a critical relation of iso-electric to ionised protein and a characteristic pH. Other critical events—e.g., lethality, if caused by ionisation—can be studied in a similar way.

Prof. **WARRINGTON YORKE** spoke strongly of the neglect in this country of research in chemotherapy.

AN AMBULANCE SERVICE FOR ETHIOPIA

BY JOHN M. MELLY, B.M. Oxon., F.R.C.S. Edin.

BEFORE describing the ambulance service which is being organised in this country to attend to the sick and wounded behind the lines of the Ethiopian army in the event of war with Italy, something must be said about the present state of medicine in Ethiopia and her existing medical resources.

THE MEDICAL RESOURCES OF ETHIOPIA

Whereas the Government has in recent years instituted a number of schools in various parts of the country where a remarkably efficient and high standard of education is maintained, no attempt has as yet been made to train native medical men. I was, however, in Addis Ababa, actually discussing with the Emperor a scheme for the foundation of a large modern hospital and medical school, when the present crisis arose. Architects' plans of a 300 bed hospital, incorporating the latest ideas in hospital construction and equipment, had been drawn up, and a complete schedule of medical education had been worked out. It had been decided that the site of the hospital, and of a medical school to accommodate 50 students, was to be at Harrar, the second largest town in Ethiopia. This scheme, of course, has had to be postponed, and in the meanwhile the inhabitants of Ethiopia, which is nearly as big as France and Spain put together, are served only by their native doctors and the European medical missionaries in the country.

The native doctors have undergone no training whatsoever in the European sense of the word. The secrets of their remedies are jealously guarded, and handed down from father to son. There is no doubt that they are in possession of powerful drugs and medicinal applications derived from local plants, but these are constantly misapplied and often do more harm than good. One extract, for example, the identity of which neither I nor any other European has yet been able to discover, apparently exerts a violent but curiously selective action upon the tissues. It appears to eat away rapidly and to a considerable depth the tissues to which it is applied, leaving a clean, granulating surface. But the remarkable thing is that this extract is said to have no action on the vessels and nerves, these remaining completely untouched. A native recently came to a mission hospital with a massive sarcoma of the neck and operative treatment was advised. He preferred to return to his native doctor who applied this extract to the whole of the affected side of his neck. He was seen at the hospital a few weeks later, and the entire tumour had apparently been eaten away, leaving a deep granulating wound in which the vessels and nerves stood out as though cleaned by careful dissection. Reports of a leaf possessing these same selective properties have come, too, from other sources. I understand that some years ago, while Sir Auckland Geddes was travelling in Uganda, close to the Ethiopian border, a similar story reached him, but that he was frankly incredulous.

In Addis Ababa there are four moderately well-equipped missionary hospitals, the largest containing one hundred beds; and there are several missionary clinics scattered through the outlying parts of the country. In Addis Ababa also the Emperor has built and supports, out of his own private purse, a small hospital equipped with a modern operating theatre and X ray plant. It is run by a capable Swedish surgeon, and two Swedish sisters, who have trained a number of very efficient native nurses. Altogether there are in the country at the most about 500 hospital beds available for the ten millions of population. Practically all of these are worked by various missionary societies.

COMMON DISEASES

The disease which probably takes the largest toll of life is typhus fever. Malaria is common in the low country, where the inhabitants have developed a considerable immunity, but Addis Ababa is situated at a height of 8000 ft. above sea-level, and consequently it and the surrounding plateau are malaria free. Tape-worm is practically universal amongst the adult population owing to their taste for eating raw meat. They deal with the situation by taking an exceedingly powerful purge, derived from local herbs, regularly once a month. Relapsing fever is common, and dysentery is very frequent, especially among the European inhabitants, unless the strictest precautions are observed. Venereal disease, both syphilis and gonorrhœa, is rife throughout the whole land, and it is said that 90 per cent. of the adult population are affected. The organisms in both cases appear to be greatly attenuated, and the tertiary forms of syphilis are rarely seen. Infant mortality under one year of age in Addis Ababa—the only place where any attempt has been made to estimate it—is reputed to be over 50 per cent. Apart from these conditions, however, the cases seen at a hospital in the capital are very similar to those seen daily in any out-patient department in London.

The native doctors—perhaps mercifully—do not practise any form of surgery; and the Ethiopian army is wholly without a medical service. In the last few weeks the skeleton of an Ethiopian Red Cross Society has been formed. The personnel, presumably, consists of one or two missionary doctors, who can ill be spared from their already understaffed hospitals, and the dozen or so Ethiopian girls who have been trained as nurses. The fighting would be, in the early stages at least, many weeks' journey from Addis Ababa, and if the Ethiopian Red Cross Society should send its personnel to attend to the wounded on the field it would of necessity leave the hospitals practically without staff. It is probably intended, however, that the doctors should remain at their hospitals and there look after any wounded who might ultimately find their way back to Addis Ababa. Meanwhile the plight of the wounded on the field of battle would beggar description. The whole country is overrun with hyenas and jackals, apart from the larger wild beasts, and there is no doubt that those wounded who survived till night falls would become a prey to these animals.

REASONS FOR THE ORGANISATION OF AN AMBULANCE SERVICE

It is for this reason—because Ethiopia has virtually no means of looking after her casualties—that an ambulance service for Ethiopia is in the process of being formed.[1] Some two months ago a number of people, most of whom have had personal knowledge of the country and can consequently visualise the more vividly the appalling prospects, formed themselves into a committee to organise medical assistance for Ethiopia in case of war. The object of the service is purely humanitarian and without political bias. The organisation will work in close coöperation with the Ethiopian Red Cross Society, and to this end Dr. T. A. Lambie, who has worked in Ethiopia for nearly thirty years and who is on the committee both of this organisation and of the Ethiopian Red Cross Society, is already on his way to Addis Ababa.

The International Red Cross Committee in Geneva has been frequently consulted and has been most helpful with advice and encouragement. They have expressed a wish to keep in close contact with the committee in London, and this is being arranged. If war breaks out and the British Red Cross Society should decide to take action, it is proposed that the ambulance service now being formed should be incorporated with them in whatever way they may think best, and its personnel and matériel and any unexpended funds would be placed at their disposal. The British Red Cross Society have stated that any steps which they may ultimately take to help the Ethiopian Red Cross Society in succouring the sick and the wounded will be taken in conjunction with the committee of this organisation. Further, the Ethiopian Minister in London has given his assurance of full authorisation by the Ethiopian government under Articles 10 and 11 of the Geneva Convention.

In the meanwhile a great deal of preliminary work and organisation has been done. Subcommittees dealing with personnel, medical equipment, commissariat, and the exceedingly difficult problem of transport, have been hard at work for some weeks. Volunteers are being interviewed daily and all preparations are being made in case of war.

PLANS

It is intended to disembark at Berbera in British Somaliland and proceed by lorry via Hargeisa and Jigjiga to Harrar where the first field hospital will be established. Casualty clearing stations will be pushed out south-eastwards from there. The line of retreat will probably be due west from Harrar in the direction of Addis Ababa, and the next situation for the field hospital is expected to be Asba Tafari in Chercher Province. An advance liaison officer under orders of the transport committee is proceeding to Berbera immediately to make preliminary arrangements there and at Harrar and along the road between the two. Since it is impossible to take any transport into Ethiopia from the Sudan till early next year owing to the condition of the roads after the rains, the only remaining route of entry, when the advancing Italians cut the Berbera-Harrar line of communication, is from Kenya via Moyale to Addis Ababa. The chief transport officer has already flown to Nairobi to open up this route and to form a committee there to deal with supplies and transport from that end.

A few more medical men are still required, but if they and sufficient funds are forthcoming in the meanwhile, it is hoped that the expedition may sail before the end of this month.

---

[1] Details are given in our advertisement columns, p. 45.

CORRESPONDENCE

THE DOCTOR AS ADMINISTRATOR

To the Editor of THE LANCET

SIR,—On its opening page the *Hospital* for September comments on the leading article entitled The Doctor as Administrator in *The Lancet* of August 10th and in very definite terms supports the appointment of lay administrators. Speaking of the medical staff of hospitals the *Hospital* remarks: "As such, their influence is very great, and no lay committee, or lay administrator, is in a position to say them nay in matters affecting medical practice." One of the chief objections to the principle of lay administration is admitted in this comment. It is surely not in the public interest that a body of experts should have all the power with regard to the purchasing of new and expensive instruments or apparatus which, often, the hospital can ill afford, and I quite agree that a lay administrator cannot safely disregard a request from a member of the medical staff. A medical superintendent, on the contrary, can, with his professional knowledge, discuss the request intelligently with one eye on the bank balance and the other on the medical and surgical requirements of a progressive hospital.

There has been much discussion of late on the question of lay versus professional administrators for hospitals. Will anyone deny that a medical man, with average business instinct and acumen, has a distinct advantage over the lay person by virtue of his having, in addition, professional training?

I am, Sir, yours faithfully,
DAVID G. MORGAN.

Llandough Hospital, Cardiff, Sept. 7th.

THE DOSAGE OF ALKALI

To the Editor of THE LANCET

SIR,—I was glad to read the letter of Dr. Geoffrey Evans in your last issue,* for, in addition to the value of the suggestions which he makes, it serves to call attention to Dr. Oakley's admirable article. Dr. Oakley showed that alkalosis is far from rare in intensive alkali treatment, and Dr. Evans replies, in effect, that it is unknown if a dose of alkali is used which is adequate without being excessive.

When Dr. Oakley's article appeared I wrote to him pointing out that in all of the cases in his article (four out of seven) in which the hæmoglobin percentage was mentioned a severe degree of anæmia (ranging from 30 to 57 per cent. hæmoglobin) was present, and that recent experience of my own had convinced me that in the development of alkalosis under alkali treatment the anæmia was the significant ætiological factor. I instanced a case in which a patient suffering from pyloric ulcer and hæmatemesis developed alkalosis under treatment. I did not at that time recognise the symptoms as such, but they were, in fact, quite characteristic. My attention was concentrated on the patient's anæmia; her hæmoglobin was only 32 per cent., but as, under appropriate treatment, the percentage of hæmoglobin increased to over 70 per cent. the symptoms of alkalosis cleared up entirely, and this in spite of the fact that the dose of alkali was maintained at exactly the same level.

Dr. Oakley's reply was interesting, for he explained that there was a sound biochemical reason for this clinical observation, since the hæmoglobin itself plays an important part in the maintenance of the acid-base equilibrium of the blood. Moreover, he had not referred to these facts in his article because he was himself elucidating the matter by giving alkali to anæmic and non-anæmic patients with peptic ulcer and observing the variations in the alkali reserve in both groups produced by the same doses of alkali.

While we await the result of this research it would appear wiser to adhere to some such prescription of alkali as Dr. Evans suggests, especially in treating patients who have had serious bleeding from peptic ulcers and are therefore anæmic—a clinical combination which is sufficiently common.

I am, Sir, yours faithfully,
Derby, Sept. 9th. DOUGLAS HUBBLE.

PROCTALGIA FUGAX

To the Editor of THE LANCET

SIR,—The interesting paper on a unique form of rectal pain which Dr. Hess Thaysen contributed to THE LANCET of August 3rd emboldens me to offer here the abbreviated history of one instance of the malady in which both cause and cure have been established.

Dr. X. Y. had long been intimately acquainted with this entity, but being in matters of personal indisposition confirmedly ostrichous (*terms, Sir, no more inadmissible* than Dr. Thaysen's "*proctalgia fugax*"), he waited 16 or 17 years before requesting a surgical colleague to examine him. This gentleman finding nothing of surgical interest suggested examination by a urologist, which latter in turn fell at once to massaging the prostate. Now the patient is not a fellow of famous faith in placebos, however well-intentioned their administration, so after two of these séances he thanked his professional friend most kindly and took refuge in lonely pondering. For many years I had been encountering him early each morning, but despite *these frequent meetings our relationship* had never progressed beyond the point of rather self-conscious and hurried mutterings when we met. I must confess that I felt he always thought me a little dull in most things, and in matters medical by no means the purist he would have liked. But *suddenly one morning* he quite overcame his diffidence or dislike and asked my professional opinion regarding this complaint of his. Hearing him recount the symptoms it seemed to me that one might connect these seizures with those occurring in certain types of "pseudo" *angina pectoris*. When I expressed what was in my mind his conduct amazed me, for he slapped me intimately on the thigh and exclaimed, "Why that's it, to be sure! Nothing could be more simple. You merely quit smoking and—well, there you are!" At any rate, *he did stop smoking and* within the week was cured.

This occurred about fourteen months ago, and I continue to see him regularly. Twice he has taken up with the weed again, and in each instance the old tormenting trouble has promptly returned. At the present writing he has not smoked since the first day of July; he is completely symptomless and vows to me that this time his resolution is of the staunchest. But, alas, I am beginning to know the poor chap so well!—I am, Sir, yours faithfully,

HARRY BECKMAN.

Marquette University, School of Medicine,
Milwaukee, Wis., U.S.A., August 26th.

To the Editor of THE LANCET

SIR,—A number of correspondents have written to you about this newly described condition. A patient of mine, male, aged 24, has been greatly troubled with it off and on for four or five years; this case is a little different from the others described in your columns because he may have an agonising rectal spasm or painful penile erection, or both. He came to me recently with both, and I gave him marked relief by blowing 20 puffs into his rectum with a Higginson syringe. The condition was not cured, but the residual pain disappeared at once when I gave him 3 minims of amyl nitrite. I feel justified in dashing into print with only one case to the credit of this drug, because its effect was so dramatic, and because it is so easily applied. A few seconds with a capsule and a handkerchief at the side of the tennis court, or in the cloak room at a dance, and all is well, and he can rejoin his party.

---

* Dr. Evans wishes to correct 47 grammes to 37 in line 20 of his letter.—ED. L.

I am, Sir, yours faithfully,

East Grinstead, Sept. 3rd.   W. H. MARSHALL.

TREATMENT OF ECLAMPTIC TOXÆMIA

To the Editor of THE LANCET

SIR,—I write to let you know of good results we have been getting in the treatment of eclampsia and pre-eclampsia at the Royal Lying-in Clinic and Midwifery School at Szolnok.

It is now ten years since Lazard introduced the treatment of pregnancy toxæmia by intravenous injection of magnesium sulphate and glucose. The effect of this treatment is primarily sedative; it controls convulsions far more surely than the Stroganoff régime—indeed, I do not remember a single case in which it has failed to stop them. It also lowers the blood pressure and has a diuretic influence. This threefold action has been responsible for excellent results, but our experience of the past two to three years suggests that these can be further improved by giving a diet rich in carbohydrates and vitamin C. This is less trying to the patients than is Volhard's "starvation diet," and while the glucose may afford valuable support to the liver in its work of detoxication, the vitamin C may counteract the factors which cause the internal hæmorrhages often found post mortem.

In pre-eclampsia the patient received each day 400 grammes of milk, with lemonade made from six lemons and 200 g. of sugar (making 1·5 litres divided into six portions). No other food was given. The results, as I have said, seemed to be improved, and in view of F. G. Dietel's demonstration (Arch. f. Gynäk., 1935, clix., 94) of serious vitamin-C deficiency in eclampsia I decided to add this vitamin in the form of ascorbic acid to the injections of magnesium sulphate and glucose. Prof. Szent-Györgyi, who first isolated this substance, puts the average therapeutic dose at 0·05 g. in 24 hours, but we know, from Vogt's successful use of it in the treatment of excessive uterine hæmorrhage in girls, that doses of 0·1 to 0·12 g. can be given without damage and with good effect. In consultation with the firm of Gedeon Richter Ltd., I decided to include 0·0125 g. of Proscorbine Richter in each ampoule of magnesium sulphate and glucose. Thus in a mild case of eclampsia if four injections sufficed to dispel all danger the patient would receive 0·05 g. ascorbic acid, while in more severe cases, requiring eight doses in the 24 hours, she would get not more than 0·10 g., and that in *dosi refracta*. The 20 c.cm. ampoules supplied to me by the firm for purposes of investigation contain 20 per cent. of pure glucose and 10 per cent. of magnesium sulphate, with 0·0125 g. of proscorbine.

The rapidity with which the combined remedy acts is really remarkable. When it was used in our usually very severe cases of eclampsia (with blood pressures of 180, 170, and 150 mm. Hg, widespread œdema, and in one case commencing œdema of lungs) albuminuria ceased, generally within three to four days, the œdema went down quickly, and the blood pressure was in all of them normal four or five days after confinement.

Since the adoption of this combined remedy we have treated 14 cases of pre-eclampsia. None of them had blood pressure under 130 and there were two with a blood pressure of 200/220. With the exception of one case (B.P. 200) in which the pressure could only be brought down to 180 we succeeded without the induction of labour; in that case labour was induced and the treatment continued, with the result that the outbreak of convulsions was avoided and the woman left the hospital quite well. We used the combined remedy in 11 of 12 cases of developed eclampsia; the other case was admitted in a hopeless condition with severe œdema of the lungs, and before anything could be done a severe convulsion brought the end. Of the 11 cases 9 were saved and 2 died of their eclampsia, though the convulsions were controlled.

If we consider the extreme severity of eclampsia in Hungary, and especially in Eastern Hungary, and the fact that nearly all the cases were transferred to us from the country (being chiefly the worst cases) the new treatment does seem to improve the outlook for the future.—I am, Sir, yours faithfully,

Szolnok, Hungary, Sept. 6th.   EUGÈNE DE KONRÁD.

WHOOPING-COUGH SKIN-TEST

To the Editor of THE LANCET

SIR,—Since the publication in your issue of August 17th of the article by Dr. Paterson, Dr. Bailey, and myself it has been pointed out to me that we do not specifically state the dose of pertussis vaccine normally used for the skin-test, the strength of the vaccine employed in the test, or the source from which the vaccine is obtainable. We should be glad therefore if you would clear up these points by publishing the following:

1. The intradermal dose for the skin-test is normally 0·1 c.cm., but it has been found in some cases that a smaller dose such as 0·05 c.cm. may give a positive result more easily read than in the case of the larger dose.
2. The vaccine for the skin-test is used at full strength (10,000 million bacilli per c.cm.) as sent out by the manufacturers.
3. The vaccine (Sauer) is prepared by Eli Lilly and Co., Ltd., and is obtainable from any pharmacy in this country.—I am, Sir, yours faithfully,

R. G. WALLER.

John Burford Carlill Pathological Laboratories,
Westminster Hospital, S.W., Sept. 6th.

ADHESIVE STRAPPING AND THE PATCH-TEST

To the Editor of THE LANCET

SIR,—I am somewhat perturbed by your annotation of August 17th on elastic adhesive strapping, particularly in the treatment of gravitational leg ulcers. I am perturbed because, judging from six years' experience in my varicose vein clinic, the dermatitis I encountered has been negligible. In this clinic all the varicose ulcers are treated with Elastoplast—more or less according to the Dickson Wright technique: and all heal rapidly with monotonous regularity. Occasionally (say 3 per cent. of cases) a little dermatitis remains on the removal of the bandage. In very mild cases these are dabbed with calamine lotion and a further elastoplast is immediately applied. In a few cases a calamine dressing is put on for 24–48 hours and then a new elastoplast bandage is applied. I have only had five cases of serious allergic dermatitis among over 4000 in which elastoplast has been applied. In three of these the eczema was confined to the legs; two had generalised allergic eczema. In every case the eczema had cleared up in six weeks.

No treatment is free from snags. The elastoplast treatment for varicose ulcer is so sure and swift, so immeasurably better than Unna's paste bandages, that the small risk of dermatitis is, in my view, negligible. Your annotation may suggest to some the possibility of abandoning elastoplast and the return to a more primitive and far less successful line of treatment. I write to ask these wavering venologists not to retrace their steps from the heights which elastic adhesive bandages have enabled them to conquer.—I am, Sir, yours faithfully,

Liverpool, Sept. 2nd. STUART MCAUSLAND.

RAW EGGS FOR INSOMNIA AND NEURASTHENIA

To the Editor of THE LANCET

SIR,—I would like to draw attention to the value of raw hen's eggs in conditions of nervous debility and irritability and especially as a remedy for insomnia. I have found them remarkably helpful in cases of the kind termed "neurasthenia" in which, without discoverable cause, there is undue fatigue, emotional imbalance, and often symptoms referred to the heart, stomach, or bowel. On an egg régime a number of patients who had previously exhausted the resources of medical treatment have reacted rapidly and recovered within a month from states bordering on invalidism. Most of those I have treated in this way during the past five years have been males between the ages of 18 and 30, and the following cases may be briefly described to illustrate the results.

1. A Burmese, aged 24, a vegetarian, complained of intractable insomnia for the previous four years. He was fairly well built and no organic trouble could be detected. His symptoms conformed to the classical picture of neurasthenia and need not be further detailed, except to say that his chief disabilities were inability to concentrate and insomnia and that occasionally he suffered from writer's cramp. Insomnia was the most distressing feature, and he was forced to have recourse to hypnotics, including bromides, chloral hydrate, paraldehyde, and morphia. These induced a non-refreshing sleep so long as they were used, but sleeplessness returned when they were discontinued. When I met the patient he was a mental and physical wreck, on the verge of suicide. He had tried almost every remedy that he could lay his hands upon, not excluding psychotherapy. In this predicament I could suggest nothing special, but just advised him to take some hen's eggs; and since his digestion was bad I recommended him to take them raw. He was to begin with eight eggs the first day; six on the second; four on the third; and two on each successive day. The eggs were to be taken in the morning before or after breakfast. The result was dramatic. He said that he had good sleep for the first time for four years and his mental concentration had greatly improved.

As this seemed interesting, it was decided to experiment on him with the following results. Insomnia returned if the eggs were discontinued. The quality and quantity of sleep was proportional to the number of eggs taken. Two eggs produced the same amount of sleep as 40 grains of bromide. The eggs, as mentioned, were taken in the morning. He felt sleepy during the day, but actually fell asleep during the night, the sleep being excessive and dreamless during the first few days as if compensating for the previous insomnia. The number of eggs had to be increased if there was greater mental or physical exertion. The eggs seemed to act only if they were taken raw. The effect was not due in any way to the caloric value of their protein, since equivalent or greater quantity of meat or other protein had no effect whatsoever.

After about four months the patient could sleep without taking eggs daily—two eggs two or three times a week being sufficient—but the sleep was always better on the day he took eggs. As he gradually recovered it was found that the hypnotic effect of eggs was manifest only if he had had insomnia the previous night. The egg treatment ended after two years, the patient having made a complete recovery. He gets insomnia only if he takes severe exercise or indulges in excessive mental exertion. A couple of eggs restores his normal sleep.

2. A Chinese, aged 30, complained of palpitation and insomnia of about three years' duration. His main trouble was that he did not fall asleep until midnight or 1 A.M. and was wide awake again by 3 or 4. No organic trouble could be detected. He was put on eggs and he improved rapidly.

3. An Englishman, aged 23, living in Cambridge, complained of intractable constipation coupled with insomnia. The trouble began when he was 18 years of age. He began to be sleepless, forgetful, and strange in manner for about a fortnight, after which he was admitted to a mental hospital, where he presented signs and symptoms of dementia præcox. He could not sleep without drugs; he was obstinately constipated and had to be relieved by enemas at first and aperients later. He was kept in hospital for about six months, and had a further month's rest before starting work. For two years he had to be relieved occasionally by salts. At the age of 21 he again had an acute relapse and was admitted to the mental hospital for dementia præcox as before. He was discharged after about three months, aperients still being required. His condition generally became aggravated each summer when he suffered from restlessness, insomnia, and fatigue, becoming unfit for much physical or mental exertion, as if on the verge of an acute relapse as before. I met him when he was 23. He was put on eggs and a few days later was able to do without aperients. He has recovered his general health and the insomnia has also disappeared. He has been taking eggs for the last nine months and has not once taken an aperient. This has been his first summer during which nothing untoward has happened; he has been capable of more physical and mental exertion than ever before, and is like any normal person. Till about eight months after he began to take eggs, the constipation usually returned if they were discontinued; but now he only takes them on alternate days or about twice a week.

4. Another Englishman, aged 32, complained of insomnia, the cause of which seemed excessive worry through business difficulties. He has been relieved by eggs. They induce diarrhœa in him, so that their use has to be stopped occasionally.

5. An Indian, aged 25, living in Burma, complained of obstinate constipation, lack of concentration, and insomnia of a year's duration. No organic cause could be detected. He was put on eggs and reported recovery after three months.

6. An Englishman, aged 20, and a Burmese student, aged 19, complained of great physical and mental exhaustion after excessive sexual indulgence. Both made a complete recovery with eggs.

7. An Englishman, aged 43, living in Cambridge, had suffered from insomnia for seven months. He also had constipation, which had to be relieved by a daily dose of salts. (It will be noticed that constipation is regularly associated with insomnia.) No cause could be assigned to the insomnia except business worry. Previously he had slept for seven or eight hours each night, but now his sleep had been reduced to two or three. If he went to sleep at 11 P.M. he was generally awake at 1 A.M.; if he went off at 1 A.M., he would be awake at 3. He had tried all sorts of remedies without avail. He was advised to take four eggs daily, with the result that he recovered his normal sleep on the third day of treatment and said he was perfectly fit for his work. His constipation has also disappeared.

In several cases a history of excessive sexual indulgence has been elicited. Mental and sexual activity seem to bear an inverse ratio one to another:

when the former increases the latter diminishes, and vice versa. A possible explanation is that the testes and nerve-cells alike require some substance which is liable to be deficient, and my own observations suggest that the deficiency is made good by administration of raw eggs. If this is true one would suppose that ingestion of large quantities of raw hen's eggs by a normal person might lead either to excessive testicular activity or increased mental activity. This is found to be so. In India eggs are generally considered to have an aphrodisiac effect, and in normal persons they increase the frequency of seminal emissions unless hard mental (or physical) activity makes countervailing demands. It is found that ingestion of eggs averts fatigue, and students preparing for examination, and athletes, report favourably on their use for this purpose. The effect seems to be more obvious—and sometimes dramatic—in exhausted people, especially those who give a history of excessive sexual intercourse.

In view of these findings I would strongly urge the wider use of raw eggs in clinical practice and also investigation into the possibility that they contain some substance with a specific effect, which could be extracted in concentrated form. To a certain extent at least this substance seems to be destroyed by heating. In treatment it is essential that the eggs be taken in the morning.—I am, Sir, yours faithfully,

Cambridge, August 29th. I. SINGH.

THE TREATMENT OF EPIGASTRIC HERNIA

To the Editor of THE LANCET

SIR,—For the past five years I have been successfully treating epigastric hernia without having recourse to the open operation. I inject the hernia instead with 2 c.cm. of a 5 per cent. solution of quinine urea hydrochloride. This obliterates the blood-vessel which is the invariable concomitant of an epigastric hernia, causes the pledget of fat to be ultimately absorbed from lack of nutrition, and leads to sclerosis with subsequent obliteration of the small hernial opening. It is strictly an office procedure and the number of treatments necessary to obtain a cure are few. If there is a subsequent recurrence one or two more injections usually suffice. This method does not necessitate any loss of time from work, which, in this day and age, means a good deal to the patient; in addition, the financial saving is, of course, considerable.

I was led to adopt this treatment by observing that a so-called epigastric hernia really consists of fat forced through the small opening in the transversalis fascia in the linea alba made by a perforating blood-vessel, together with the blood-vessel itself. There is never a distinct hernial sac, and if one is careful while operating to remain in the mid-line the abdominal cavity will never be opened. The reason why epigastric hernia is so seldom diagnosed is simple. In ordinary palpation of the abdomen it is the surgeon's aim to obtain complete relaxation of the abdominal wall. The exact opposite is necessary in order to demonstrate an epigastric hernia. With the patient lying supine, he is directed to lift the head and shoulders off the examining table so as to put a strain on the abdominal muscles. This will cause a slight divarication of the recti muscles. Now gently palpate with the tip of the examining finger the whole length of the linea alba from the ensiform cartilage to the umbilicus. If an epigastric hernia is present a small depression will be found containing a small soft mass which is fairly tender on even light pressure.

If the onset of epigastric hernia is acute there may be extreme pain and even some abdominal rigidity—the latter however being more apparent than real. I remember seeing a man who was about to be operated upon for a supposed perforated gastric ulcer. He had previously had two other abdominal operations—one for removal of a so-called chronic appendix. His onset of symptoms was sudden and extremely acute, with vomiting, pain, and apparent rigidity. There was however no rise of temperature or pulse-rate, no decrease of liver dullness, and no alteration of the leucocyte count. Careful examination showed a small epigastric depression extremely tender to even light pressure. I injected some novocain into the area and in five minutes he was free from distress. Needless to say, his abdomen was not opened. There is often associated with epigastric hernia a dragging pain described as if the "back were pulled forward into the stomach," which causes the patient to flex the spine so as to decrease the pull on the recti muscles. Such cases may be treated intermittently for months or even years for gastritis or indigestion without obtaining the slightest benefit. When the true condition is diagnosed and appropriate treatment instituted, the relief is immediate.

I am, Sir, yours faithfully,

H. F. W. WARDEN.

Detroit, Michigan, U.S A., August 19th.

AUSTRALIA

(FROM OUR OWN CORRESPONDENT)

DEVELOPMENTS OF CANCER CONTROL IN AUSTRALIA DURING 1934

A REVIEW of the attempts at cancer control in Australia during 1934 was presented to the Sixth Australian Cancer Conference held at Canberra, from May 14th–17th, by Dr. M. J. Holmes, senior medical officer, Commonwealth Department of Health, and is now published in the August issue of the *Journal of the Cancer Research Committee.* At present the control of cancer in Australia is limited to organisations in each separate State; the formation of a federal body has been considered but has not been adopted. In New South Wales, during the year, the senate of the University of Sydney relinquished control of the Commonwealth radium, which was distributed to a number of hospitals. The university still continues to hold some radium which is used for research purposes and the production of radon. A committee for study and treatment of cancer has been formed in Sydney and new clinics have been established at Royal North Shore and the Prince Henry Hospitals. In Victoria a public meeting was called by the Premier to discuss the promotion of a State organisation for the control of cancer, and although it was decided to form this body and its objects were defined and a scheme drafted, no further progress has been made. The Melbourne and St. Vincent's Hospitals report expansion of their radiotherapeutic departments and the Austin Hospital, which provides the largest and best accommodation for cancer cases in Victoria, has increased its cancer accommodation from 83 to 130 beds. A clinic for the treatment of cancer of the cervix uteri and of the breast has been opened at the Prince Henry Hospital, Melbourne. In Tasmania two committees, one in the North and one in the South, are now functioning as units of the Tasmanian Anti-Cancer Campaign, the latter committee having been formed during 1934. It is proposed to instal a deep ray therapy plant at the Launceston Hospital. In Western Australia, the principal development has been the establishment of a radon laboratory at the University of Western Australia. In other States no changes are reported. During the year the Commonwealth Radon Laboratory issued 23,210 millicuries of which all, except 1250 units issued for research purposes, was used for treatment, 92 per cent. being issued mounted in needles.

TREATMENT OF INFANTILE PARALYSIS

Many of the differences between those interested in the trial of the method of treating infantile paralysis devised by Sister Kenny have now been satisfactorily composed.[1] At present Sister Kenny is in personal charge of three centres, one at Townsville, one at Brisbane, and one about to be opened at the Royal North Shore Hospital, Sydney. It is believed that a clinic may be opened at the Children's Hospital, Frankston, Victoria, but no definite announcement to this effect has yet been made. The work done at the Sydney clinic is being watched by two committees, one appointed by the Commonwealth and one by the State Government. These committees are to examine cases before and after treatment and to report on the method and its value. In the *Australian Hospital* for June, 1935, there appeared a letter from Dr. James V. Guinane to the chairman of the Hospitals Commission, Sydney, which contained the first detailed account of the method to be published. Dr. Guinane, who has spent many months observing the method, considers that the régime introduced by Sister Kenny is a definite step forward in the treatment of infantile paralysis. He states that: (1) no splints, plaster, or other methods of immobilisation are used; (2) all the joints of the body are moved through their full range, at least once daily; (3) the patient is encouraged to perform movement under the guidance of and with the assistance of the attendant's hands when a movement cannot be performed unaided; as the performance of a movement gains in strength it is resisted so that the recovering muscle is subjected to gradually increasing load; (4) no exercises beyond those prescribed are allowed. The advantages of the absence of splintage are held to be avoidance of (1) stiffness in the joints or disuse atrophy of the muscles, (2) interference with the blood-supply to the parts, (3) any feeling of helplessness or hopelessness engendered in the patient by immobilisation of a limb. The use of active rather than passive movements gives the patient confidence and the movement itself increases the blood-supply. The conclusions reached by Dr. Guinane seem to be that the method is suitable only for cases of infantile paralysis and spastic paralysis and that, as might be expected, the best results are achieved in the earliest cases. Improvement is in his view quicker and greater than when the orthodox methods of treatment current in Australia are used even if cases are not seen very early, but the treatment is of no value in really advanced cases. These claims are much more modest than those originally made for this method. The aspect of the whole matter which continues to puzzle medical men is why it is shrouded in so much mystery and why even Dr. Guinane seems to think that the method must gain recognition before the details are made known. It is understood, however, that a book written by Sister Kenny is at present being printed in Brisbane, and it is to be hoped that it will provide a full account of her method.

PANEL AND CONTRACT PRACTICE

What is Manual Labour?

IT might have been thought that after 22 years there would have been little doubt as to what classes of persons were insurable and what classes were not. We learn, however, from the sixteenth annual report of the Ministry of Health that for the first time for many years a question was submitted for decision directly to the High Court under Section 89 (1) of the Act of 1924. The question referred was whether the employment of a professional footballer is to be regarded as employment by way of manual labour. It will be remembered that the income limit of £250 a year applies only to non-manual workers; for manual workers there is no income limit. It has long been held that professional footballers and cricketers were manually employed, this view being based on certain pronouncements of the Court of Appeal in a case arising out of the Workmen's Compensation Act, but certain observations that fell from a judge in the course of an appeal concerning the employment of an acrobat made it apparent that the question whether a professional footballer is, in fact, employed "by way of manual labour" was one upon which it was expedient to obtain the specific guidance of the High Court. The decision was that the employment was not "by way of manual labour" and that the player, therefore, since the rate of his remuneration exceeded £250 a year, was not required to be compulsorily insured.

Regional Medical Service

The paragraphs in the report on the regional medical scheme are of more than passing interest. The total number of references for advice as to incapacity for work in 1934 was 468,476, of which only 2304 were referred by insurance doctors, the remainder coming from approved societies. Of these references 181,220, or 39 per cent., related to men and 287,256, or 61 per cent., to women. The number of persons actually examined on incapacity references was 246,088. The number who were reported to have received a final certificate before the date fixed for examination was 134,678, and 86,628 others did not attend for examination. Of the persons examined 179,010 were reported as incapable and 67,078 as not incapable of work. Consultation references numbered 1361, 70 only of them being from insurance doctors. These figures speak for themselves. They tell us just what it is that keeps the regional medical staff busy all day and every day. And occasionally the onlooker will be constrained to ask: Is it inevitable? or Is it worth while?

Doctors and Chemists

In 1934 there were 15,500 doctors in insurance practice, and medicine and appliances were available as part of medical benefit at about 10,000 chemists' shops to approximately 14,973,000 insured persons entitled to medical benefit. The cost of medical benefit was £8,514,000, of which sum insurance doctors received over £6,175,000 and £1,861,160 of the balance was paid to insurance chemists for the supply of drugs and appliances. The remainder was expended as to £204,000 to insurance doctors in rural areas on account of mileage ; as to £194,000 to doctors for medicine and appliances supplied by them personally or for medicines dispensed by them in country districts where patients are out of reach of chemists ; as to £64,200 on account of insured persons who exercised their option to claim medical benefit through approved institutions ; something over £8000 was set aside to enable country doctors to attend courses of post-graduate study and to provide them with other desirable facilities such as telephones, motor-cars, branch surgeries, or reasonable vacations ; while £7550 was paid on account of insured persons who were required or allowed to make their own arrangements for medical benefit. Of the sum of £8000 referred to above, £2354 was expended in grants which enabled 86 doctors to attend short courses of post-graduate study, but this facility is restricted to insurance doctors in sparsely populated rural districts.

There was a decrease of 2·3 per cent. in the number of insurance prescriptions dispensed in 1934 compared with the previous year, the numbers falling from 59,338,504 to 57,986,980, and the average number of prescriptions issued per insured person entitled to supplies decreased from 4·56 to 4·49. The decline in the number of prescriptions dispensed was less than might have been expected in a year of freedom from severe influenza, and the report states that the continuance of this high frequency is a matter of concern to the department. The total of the chemists' accounts fell from £1,985,885 to £1,941,874. The average ingredient cost per prescription rose from 3·643 pence to 3·677 pence, but the average total cost of drugs and prescribed appliances for insured persons entitled to obtain them from chemists fell from 2*s.* 11½*d.* to 2*s.* 11*d.*

Prescribing Excessive?

The number of cases in which it has been found necessary to withhold money from doctors on account of excessive prescribing continues to be low as compared with the number of cases in which prescribing has been reviewed or has been investigated under the more formal manner prescribed under the regulations. Regional medical officers paid 928 visits to insurance doctors in England where the doctors' prescribing appeared to call for explanation, and in only a small number of cases did this exchange of view fail to enable the Minister either to accept the explanation offered by the doctors, or to satisfy himself that relatively minor departures from a reasonable standard of prescribing would not recur. In ten cases the Minister found it sufficient to inform the doctors that, while it appeared to him that notwithstanding their explanation there was a prima-facie case for referring the matter to the panel committee, he would refrain from that course because he was satisfied of their intention not to give occasion for such reference to be considered in the future. In four cases the Minister felt it necessary, after considering the explanations given by the doctors, to refer to panel committees the question whether the doctors' prescribing had imposed charges on the available funds in excess of what was reasonably necessary. In all four cases the panel committees found that an excess cost had been so imposed during the quarterly periods which were the subject of investigation. The estimated amounts of excess cost ranged from £12 10*s.* to £30. None of these findings was made the subject of appeal. After considering the recommendation of the insurance committees made in the light of the findings of the panel committees, and giving the doctors concerned an opportunity of making oral or written representations, the Minister withheld money during the year from the remuneration of doctors in three cases, the sums withheld being £10, £7, and £3 respectively.

PUBLIC HEALTH

Another Case of Botulism

Dr. Edwin Smith, the Hammersmith coroner, held on Monday an adjourned inquest on the body of a commercial traveller, aged 55, and the jury returned a verdict of "Death by misadventure due to the toxic poisoning of botulism." The dead man's wife testified that on Wednesday, August 14th, she made for her husband a meat pie, of which a little was still left over on the following Sunday, the intervening period having been very hot. She thought, but was not sure, that he did eat some of the stale pie on the Sunday. After a period of three or four days, during the early part of which the patient vomited, and the bowels remained obstinately closed, he was admitted to Hammersmith Hospital. He was then conscious but in some distress, with complete ophthalmoplegia, marked weakness of the muscles of the tongue and throat, and extreme dryness of mucous membranes. Temperature and pulse were normal, and he could speak, although indistinctly. Botulinus antitoxin was given intravenously about three hours later. Death occurred seven hours after admission, apparently from combined failure of respiration and circulation. Dr. A. A. Miles, reader in bacteriology at the British Postgraduate Medical School, in his evidence said he had examined the gravy submitted to him. Cultures from it had yielded filtrates toxic to mice, the toxicity being neutralised by botulinus antitoxin. Search is still being made for the infecting organism. Sir Bernard Spilsbury said he thought that botulism was clearly established as the cause of death. Vegetables are, he remarked, likely to be contaminated if they have been insufficiently cooked and then left in very hot weather. The case is of particular interest as being the only one so far established in this country in which fatal botulism has resulted from food cooked in the home. How under these circumstances it came about that the organism which only develops its fatal toxin under anaerobic conditions was able to do so remains for further investigation.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 31ST, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0 ; scarlet fever, 1781 ; diphtheria, 913 ; enteric fever, 81 ; acute pneumonia (primary or influenzal), 384 ; puerperal fever, 34 ; puerperal pyrexia, 95 ; cerebro-spinal fever, 14 ; acute poliomyelitis, 34 ; acute polio-encephalitis, 2 ; encephalitis lethargica, 6 ; dysentery, 11 ; ophthalmia neonatorum, 72. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Sept. 6th was 2585, which included: Scarlet fever, 761; diphtheria, 910; measles, 39; whooping-cough, 404; puerperal fever, 29 mothers (plus 12 babies); encephalitis lethargica, 270; poliomyelitis, 13. At St. Margaret's Hospital there were 25 babies (plus 12 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 3 (0) from measles, 3 (0) from scarlet fever, 21 (4) from whooping-cough, 27 (3) from diphtheria, 60 (13) from diarrhœa and enteritis under two years, and 12 (3) from influenza. The figures in parentheses are those for London itself.

Deaths from diarrhœa and enteritis were scattered over 30 great towns, the highest numbers being Liverpool 9, Southampton, Leeds, and Nottingham each 3, no other great town more than 2. The 3 fatal cases of measles were at Liverpool. Birmingham reported 4 deaths from whooping-cough; the remaining fatal cases were scattered singly over the country. No great town reported more than 2 deaths from diphtheria.

The number of stillbirths notified during the week was 290 (corresponding to a rate of 44 per 1000 total births), including 35 in London.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdrs. T. Madill to *Orion* as Squadron M.O., and W. E. Heath to *Victory* for R.N.B.

Surg. Lt.-Comdrs. A. L. McDonnell, S. G. Weldon, and W. G. C. Fitzpatrick to rank of Surg. Comdrs.

Surg. Lt.-Comdrs. E. J. Mockler to *Pembroke* for R.N. Hosp., Chatham, and T. L. J. Barry to *Londonderry*.

Surg. Lt.-Comdrs. (D.) T. G. A'C. Emberson to *St. Vincent*, P. S. Turner to *Ganges*, and L. V. Donegan to *Pembroke* for R.N.B.

Surg. Lt. W. M. Greer promoted to Surg. Lt.-Comdr.

Surg. Lts. H. L. Cleave and C. N. H. Joynt to *Drake* for R.N.B., H. J. Bennett to *Pembroke* for R.N.B., and R. H. A. Turner to *Queen Elizabeth* and to *Resolution* (on transfer of flag).

ROYAL AUSTRALIAN NAVAL RESERVE

The King has approved of the award of the Volunteer Officers' Decoration to Surgeon Commander Percy Gerald Shelton, M.B., B.S.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt.-Comdr. H. P. Widdup to *Pembroke* for R.N. Hosp., Chatham.

Surg. Lt.-Comdr. J. E. Purves's resignation accepted.

Surg. Lt. D. Q. Bawtree promoted to Surg. Lt.-Comdr.

Surg. Lt. E. R. G. Passe to be Surg. Lt.-Comdr.

Surg. Sub-Lt. K. E. O. Ringdahl to be Surg. Lt.

Proby. Surg. Lt. J. L. Dunlop to be Surg. Lt.

Proby. Surg. Lt. E. J. S. Woolley to *Pembroke* for R.N.B.

Proby. Surg. Sub-Lt. R. E. King to *Pembroke* for R.N. Hosp., Chatham.

ROYAL ARMY MEDICAL CORPS

Lt.-Col. W. A. Spong retires on ret. pay.

Maj. and Bt. Lt.-Col. J. G. Gill, D.S.O., O.B.E., M.C., to be Lt.-Col.

Short Serv. Commissions.—The undermentioned Lts. (on prob.) are confirmed in their rank: A. MacLennan, I. U. Young, J. O'Connell, E. J. Pryn, R. Phillipson, P. L. E. Wood, L. E. Odlum, J. G. M. A. Brunet, R. O. A. Leroux, B. d'E. Barclay, N. I. McLeod, G. S. Musgrove, P. R. Wheatley, A. C. Cox, J. J. Groome, J. S. Kelleher, C. Ryan, J. McN. Lockie, W. B. Hamilton, D. S. Cochran, T. P. O'Brien, N. A. Flaherty, and J. P. Weir.

ARMY DENTAL CORPS

Bernard Edward ffrench is granted a temp. commn. in the rank of Lt.

TERRITORIAL ARMY

Col. W. A. Thompson, T.D., retires on completion of tenure as A.D.M.S., 50th (Northumbrian) Div., and retains his rank.

Lt.-Col. and Bt. Col. R. Errington, M.C., M.D., to be Col. and A.D.M.S., 50th (Northumbrian) Div.

Capt. A. O. Bekenn to be Maj.

Capt. D. G. Robinson resigns his commn.

ROYAL AIR FORCE

Flying Offr. H. L. Willcox to No. 6 Flying Training School, Netheravon.

INDIAN MEDICAL SERVICE

Maj. R. A. Warters to be Lt.-Col.

Lt. (on prob.) G. P. Charlewood to be Capt. (on prob.).

The undermentioned officers retire: Col. A. H. Proctor, D.S.O., and Lt.-Col. K. G. Gharpurey.

The undermentioned appt. has been made in India: *D.A.D.M.S.*—Maj. P. F. A. Grant, O.B.E., I.M.S.

The Commander-in-Chief has approved the following appointments in India: Col. W. T. McCowen as Assistant Director of Medical Services, Baluchistan District, and Lt.-Col. S. G. S. Haughton, O.B.E., to act for him while on leave.

COLONIAL MEDICAL SERVICE

A. D. Williamson, M.B., Ch.B., F.R.C.S., has been appointed Ophthalmic Surgeon and Physician, College of Medicine, Singapore, Straits Settlements; and Dr. D. R. Griffith (Medical Officer, Achimota College) becomes Medical Officer, Gold Coast.

Births, Marriages, and Deaths

BIRTHS

CASHELL.—On Sept. 6th, at Reading, the wife of Willoughby Cashell, M.B. Lond., of a son.

EDMONDSON.—On Sept. 1st, the wife of E. L. Edmondson, M.R.C.S. Eng., Leamington Spa, of a daughter.

HUTCHINSON.—On Sept. 4th, at Haywards Heath, Sussex, the wife of H. Procter Hutchinson, M.B. Camb., of a son.

RIDDELL.—On Sept. 5th, at Baldock, Herts, the wife of D. Renton Riddell, M.B. Leeds, of a son.

VALENTINE.—On Sept. 3rd, at Green-street, W., to Lady Freda, wife of F. C. O. Valentine, M.R.C.P. Lond.—a son.

WILCOX.—On Sept. 1st, at King's Lynn, the wife of S. Murray Wilcox, M.R.C.S. Eng., of a son.

MARRIAGES

BARRETT—WRIGHT.—On Sept. 3rd, at St. John the Divine Church, Leicester, John Oridlan Barrett, V.C., F.R.C.S. Eng., to Ernestine Helen, only child of Mr. Ernest Wright of Birstall, Leicestershire.

HUGHES—SMITH.—On Sept. 5th, at the Catholic Cathedral, Shrewsbury, William Stanley Hughes, M.B. Lond., to Elizabeth Patricia Smith, widow of Walter R. H. Smith, M.D., of Bicton Heath.

PEARCE—WALLACE.—On Sept. 7th, 1935, at Chelsea, James G. Pearce, M.Sc., M.I.E.E., F.Inst.P., to May Isabel Wallace, M.B., Ch.B. Birm., D.P.M.

TAYLOR—ROBINSON.—On Sept. 7th, at St. Peter's Church, Ealing, Wallace Antony Frederic Taylor, M.R.C.S. Eng., to Beryl, daughter of Major R. A. Robinson of Ealing.

TERRY—HALSTEAD.—On August 31st, at Mill Hill Chapel, Leeds, James Oliver Terry, M.B. Leeds, M.R.C.P., to Dorothy Halstead, M.Sc., M.B. Leeds, eldest daughter of Mr. and Mrs. T. Halstead of Rodley.

DEATHS

DORGAN.—On Sept. 1st, at Flagstaffe House Convalescent Hospital, Southport, James Dorgan, M.B. R.U.I., D.P.H., Lt.-Col. R.A.M.C., retd., superintendent of the hospital.

HAMILTON.—On Sept. 1st, at Southampton, Herman Lauder Hamilton, M.B. Aberd., D.P.H., in his 60th year.

ROSE.—On Sept. 1st, at Aberdeen, George Rose, M.B. Aberd., D.P.H., aged 80.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

BOVEY TRACEY HOSPITAL.—Miss Violet Wills has laid the foundation-stone of a children's jubilee ward at this hospital.

MEDICAL NEWS

University of Cambridge

Dr. J. A. Ryle has been appointed regius professor of physic in the university in succession to Sir Walter Langdon-Brown.

John Alfred Ryle, the son of Dr. R. J. Ryle of Brighton, was born in 1889 and educated at Brighton College and Guy's Hospital medical school. He graduated M.B. Lond. in 1913, being awarded the gold medal of the university. When war broke out he was released from his third resident appointment at Guy's to join the R.A.M.C. (S.R.) and served as a captain in France and Belgium from 1914 to 1918. He returned to Guy's in 1919 as medical registrar, and in the same year took his M.D., receiving another gold medal. He acted as assistant in the children's department and Astley Cooper assistant to the curator of the Gordon Museum until 1920, when he was appointed assistant physician to the hospital and demonstrator in morbid anatomy and medical pathology. Dr. Ryle was elected a fellow of the Royal College of Physicians of London in 1924, and the following year was chosen to deliver the Goulstonian lectures on Gastric Function in Health and Disease, published in our columns and later in book form; and in 1932 gave a Hunterian lecture on the Natural History of Duodenal Ulcer to the Royal College of Surgeons of England. In 1929 he became physician to Guy's, and in 1932 he was appointed physician to His Majesty's Household. Dr. Ryle's contributions to medical literature have covered a wide range, including philosophical reviews as well as original contributions to medical science, notably in connexion with diseases of the intestinal tract and the cardiovascular system.

British Congress of Obstetrics and Gynæcology

The 1936 meeting of the British Congress of Obstetricians and Gynæcologists will be held in Belfast from April 1st to 3rd under the presidency of Prof. R. J. Johnstone. The subject for discussion will be conservative treatment, by operation or otherwise, of pathological conditions of the ovaries, tubes, and uterus, with special reference to functional results. Mr. C. H. G. Macafee, 18, University-square, Belfast, is the local scientific secretary.

Central London Throat, Nose, and Ear Hospital

A course in methods of examination and diagnosis will be held at this hospital from Sept. 30th to Oct. 4th at 4.30 daily. A course in anatomy and physiology for Part I. of the D.L.O. examination will be given by Dr. Archibald Durward from Oct. 7th to Oct. 19th, while a clinical course for Part II. has been arranged to take place from Oct. 21st to Nov. 2nd.

The annual address of the hospital will be given at 4 P.M. on Friday, Oct. 11th, by Mr. A. Brown Kelly, consulting surgeon for diseases of throat and nose at the Victoria Infirmary, Glasgow. He will speak on the œsophagus in young children. The usual Friday lectures, to which medical visitors are invited, will be held throughout the winter and will be announced in our Weekly Diary.

King's College Hospital

Lectures and demonstrations, open to all medical practitioners, will be held at this hospital on Saturday, Oct. 5th, from 11 A.M. to 6 P.M., and on Sunday morning, Oct. 6th, before the beginning of the new session. The annual dinner of past and present students will take place at 8 P.M. on Oct. 5th at the Mayfair Hotel, London, W., with Sir Charlton Briscoe in the chair. The inaugural lecture will be given at 4.30 P.M. on Thursday, Oct. 10th, by Dr. G. F. Still. From Oct. 3rd to Dec. 12th a post-graduate course of lectures on tuberculosis will be given at the medical school on Thursdays at 9 P.M., to which practitioners are also invited.

Welsh National School of Medicine, Cardiff

On Sept. 4th the Merioneth county council received a deputation asking that the rate-aided contributions to the school from the county should be resumed. Dr. Joyce, pro-chancellor of the University of Wales, spoke of the importance of medical services and said that a united Wales should stand behind a national institution. Mr. Jenkin James, secretary of the school, said that if Merionethshire decided to resume contributions it was probable that Newport borough and Radnor county council would fall into line, and this would mean an increase of £400 in the income of the school. After discussion the council unanimously agreed to resume payments.

A PORTRAIT of Sir Robert Jones, intended to commemorate his work and that of Hugh Owen Thomas, was unveiled by Dame Agnes Hunt on Sept. 4th at the Ceiriog Memorial Institute at Glyn Ceiriog.

THE meeting of the Continental Anglo-American Medical Society arranged for Oct. 5th in Paris has been postponed indefinitely.

University of Liverpool

Dr. H. H. Stones has been appointed Louis Cohen professor of dental surgery and director of dental education at the university in succession to Prof. W. H. Gilmour, who has retired. Dr. Stones is honorary dental surgeon to University College Hospital dental school, and has been in practice in London and St. Leonards.

Middlesex Hospital Medical School

The annual refresher course for former students of this school will begin on Saturday, Sept. 28th, at 2.15 P.M., and continue up to the evening of Oct. 1st. The annual dinner for past and present students and their friends will be held on Tuesday, Oct. 1st. at the Savoy Hotel, at 7 for 7.30 P.M. Dr. H. Campbell Thomson will take the chair.

London Hospital

Sir William Goschen, chairman of this hospital, spoke at a meeting of the court of governors of his own experience, as a patient, of the efficiency of the administration of the hospital. He detailed the scheme to erect a block for paying patients so that persons of moderate means might have the benefits of the skilled treatment that the hospital could offer.

Hull Contributory Scheme

In the five years this scheme has existed over £100,000 has been given to the hospitals taking part. The present membership totals 67,000, and this is by no means regarded as saturation point, especially in the rural districts.

Donation to Radcliffe Infirmary, Oxford

Lord Nuffield has given £8000 to this hospital for the construction of a new medical ward and accommodation for its nursing staff.

Stratton Cottage Hospital

The wards in this hospital, said to be the second oldest cottage hospital in the country, had become out of date and the Bishop of Truro recently opened a large modern ward and two private wards there.

Child Guidance in Sheffield

An address was given by Dr. William Moodie, medical director of the London Child Guidance Clinic, at a meeting held recently at the University of Sheffield, to consider what could be done to provide a child guidance clinic for the city. A committee was appointed to consider the question, which included the following medical members: Dr. Thomas Chetwood, Prof. A. E. Naish, Dr. Helen Wilson, Dr. E. Fretson Skinner, Dr. Arthur Pool, Dr. F. E. E. Schneider, Dr. A. G. Yates, and Dr. Annie Greenep.

Institute of Medical Psychology

Five seminars on fundamental psychological conceptions will be given by Prof. C. G. Jung of Zurich from Sept. 30th to Oct. 4th at 7.45 P.M. at the institute. The meetings will be open to medical graduates and to professors, readers, and lecturers of the University of London. Application for tickets should be made in advance to the educational secretary of the institute, Malet-place, London, W.1.

Other courses to be held during the year include a five weeks' introductory course on psychotherapeutic theory and method which will be given on Monday and Thursday afternoons from Oct. 7th to Nov. 7th; a post-graduate course on this subject will also start on Oct. 7th, and during the session will cover the work required for the D.P.M. On Tuesdays, from Oct. 22nd to Dec. 10th, at 6 P.M., Dr. Emanuel Miller will lecture on problems of parenthood.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Sept. 16th, to SATURDAY, Sept. 21st.—WESTMINSTER HOSPITAL. All-day post-graduate course in medicine and surgery. (Men only.)

Appointments

KERSHAW, J. D., M.B. Lond., D.P.H., has been appointed Medical Officer of Health for Accrington.

PATTERSON, W. G., M.D. Edin., M.R.C.P. Lond., D.P.H., Medical Officer of Health for Barnsley.

West End Hospital for Nervous Diseases.—The following appointments have been made:—

GOITEIN, P. L., M.B. Lond., D.P.M., Hon. Medical Psychologist to the Child Guidance Unit.

LLOYD, J. E. SETON, M.B. Liverp., D.P.M., Hon. Clinical Psychologist to the Out-patient Department.

LUCAS, R. E., M.B. Brist., Hon. Medical Psychologist to the Child Guidance Unit.

Vacancies

For further information refer to the advertisement columns.

Aberdeen Royal Hospital for Sick Children.—Hon. Asst. Surgeon to Ear, Nose, and Throat Dept.
Aberdeen Royal Infirmary.—Hon. Jun. Asst. Surgeon to Ear, Nose, and Throat Dept.
Abyssinia Ambulance Unit.—Volunteers.
Altrincham General Hospital.—Sen. and Jun. H.S.'s. £150 and £120 respectively.
Aylesbury, Royal Buckinghamshire Hospital.—Second Res. M.O. At rate of £150.
Bath and Wessex Children's Orthopædic Hospital, Combe Park.—H.S. At rate of £120.
Bath Royal United Hospital.—H.S. At rate of £150.
Birmingham and Midland Eye Hospital.—H.S. At rate of £130.
Birmingham, Dudley-road Hospital.—Jun. M.O. At rate of £200.
Bolton Royal Infirmary.—H.S. £125.
Bradford Children's Hospital.—H.S. £100.
Bradford City.—Asst. School M.O. £500.
Bradford Royal Eye and Ear Hospital.—Jun. H.S. £160.
Brighton, Royal Alexandra Hospital for Sick Children.—H.S. £120.
Bristol, Southmead Municipal Hospital.—Asst. Res. M.O. £250.
British Empire Cancer Campaign, 12, Grosvenor-crescent, S.W.—Assts. for Cancer Research Laboratory. Each £350 to £400.
Cancer Hospital, Fulham-road, S.W.—Asst. Radiologist. £350.
Chester County Mental Hospital.—Jun. Asst. M.O. £350.
Chester, East Lancashire Tuberculosis Colony, Barrowmore Hall.—H.P. At rate of £150.
Coventry and Warwickshire Hospital.—Res. H.S. Also Cas. O. Each £125.
Derbyshire County Council.—Tuberculosis Officer. £750.
Doncaster Royal Infirmary.—H.S. to Eye and Ear, Nose and Throat Depts. £175.
Doncaster Royal Infirmary and Dispensary.—Sen. Res. £250. Also Res. Anæsthetist. At rate of £175.
Dreadnought Hospital, Greenwich, S.E.—Med. Supt. £250
—Asst. Welfare M.O. £500.
M.O.H. £600.
Memorial Hospital.—Res. H.S. £150.
an-street, E.—Gynæcologist.
ospital, Shrewsbury-road, E.—H.S. to
s. O. At rate of £120.
Edinburgh Royal Infirmary.—Clin. Asst. for Ear, Nose, and Throat Dept. £105.
Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Surg. Reg. £100.
Evelina Hospital for Sick Children, Southwark, S.E.—H.P. At rate of £120.
Fareham, Hants, Knowle Mental Hospital.—Jun. Asst. M.O. £350.
Gloucestershire Royal Infirmary.—H.P. At rate of £150.
Gloucestershire Royal Infirmary and Eye Institution.—Res. Surg. O. At rate of £200.
Guildford, Royal Surrey County Hospital.—Res. Surg. O. £250. Also H.P. and Cas. O. £150.
Halifax Royal Infirmary.—Res. Surg. O. At rate of £250.
Hospital for Sick Children, Great Ormond-street, W.C.—Research Fellow for Morbid Anatomy. £500. Res. Med. Supt. £300. Asst. M.O. £300. Also Out-patient Med. Reg. £250.
Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W.—Res. H.S. At rate of £75.
Hove General Hospital.—Res. M.O. At rate of £150.
Huddersfield Royal Infirmary.—H.S., H.P., and Res. Anæsthetist. Each at rate of £150.
Huddersfield, St. Luke's Hospital.—Res. M.O. £200.
Ilford, West Ham Mental Hospital, Goodmayes.—Jun. Asst. M.O. £350.
King's College Hospital, S.E.—Registrar to Ear, Nose, and Throat Dept.
Leicester Royal Infirmary.—Jun. Res. Anæsthetist. At rate of £150. Also Sen. Cas. O. £125.
Leicestershire County Council.—Asst. County M.O.H. £700.
Liverpool County Borough.—Two Jun. Asst. School M.O.'s. Each £500.
Liverpool, County Mental Hospital, Rainhill.—First Asst. M.O. £700. Second Asst. M.O. £650.
Liverpool Royal Babies' Hospital, Woolton.—Res. M.O. At rate of £90.
Maidstone, Kent County Ophthalmic and Aural Hospital.—Ophth. H.S. At rate of £200.
Maidstone, West Kent General Hospital.—Two H.S.'s. Also H.P. Each £150.
Manchester, Ancoats Hospital.—H.S. for Ear, Nose, and Throat Dept. At rate of £100.
Manchester, Booth Hall Hospital.—Jun. Asst. M.O. At rate of £200.
Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Res. M.O. for Ear, Nose, and Throat Dept. £200.
Mansfield, Harlow Wood Orthopædic Hospital.—Two H.S.'s. Each at rate of £200.
Margate and District General Hospital.—Res. M.O. £150.
Middlesbrough Education Committee.—Sen. Asst. School M.O. £500.
Middlesbrough, North Ormesby Hospital.—Hon. Orthopædic Surgeon.
Middlesbrough, North Riding Infirmary.—Third H.S. £125.
New Zealand, University of Otago and Dunedin Hospital.—Sen. Res. M.O. £500.
Northampton General Hospital.—Hon. Obstet. Surgeon. At rate of £150.
North Riding of Yorkshire County Council, &c.—Two M.O.H.'s. Each £800.
Norwich, Jenny Lind Hospital for Children.—Res. M.O. £120.
Norwich, Norfolk and Norwich Hospital.—H.P. £120.
Nottingham General Dispensary, Gregory Boulevard Branch.—Res. Surgeon. £250.
Nottingham General Hospital.—H.S. for Ear, Nose, and Throat Dept. Also Cas. O. Each at rate of £150.
Plymouth Education Committee.—Asst. School M.O. £500.
Princess Elizabeth of York Hospital for Children, Shadwell, E.—H.P. At rate of £125.
Queen's Hospital for Children, Hackney-road, E.—H.P. and Cas. O. Each at rate of £100.
Reading, Royal Berkshire Hospital.—Res. H.P., Res. Cas. O., also Res. M.O. for Blagrave Branch Hospital. Each at rate of £125.
Richmond Royal Hospital.—Jun. H.S. At rate of £100.
Rotherham Hospital.—Cas. H.S. £150.
Royal London Ophthalmic Hospital, City-road, E.C.—Sen. Res. Officer. £150.
St. Mary's Hospital, W.—Surg. Reg. £200. Also Obstet. Reg. and Jun. Clin. Asst. for X Ray Dept. Each £50.
St. Thomas's Hospital, S.E.—Surgeon. Also Surgeon to Out-patients.
Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. At rate of £100.
Sheffield, Jessop Hospital for Women.—Two H.S.'s. Each at rate of £100.
Sheffield Royal Infirmary.—Clin. Asst. for Dermatological Dept. £300.
Sidcup, Queen Mary's Hospital.—Asst. M.O. £350.
Southampton.—Part-time Antenatal M.O., Gyn. and Con Obstet. At rate of £300.
Southend-on-Sea General Hospital.—H.S. At rate of £100.
Stamford, Rutland and General Infirmary.—H.S. At rate of £250.
Swanley, Kent, Alexandra Hospital for Children.—Res. Asst. M.O. At rate of £200.
Swansea General and Eye Hospital.—H.P. Also Temp. H.S. Each at rate of £150.
University College Hospital, Gower-street, W.C.—Tuberculosis Officer. £300.
West End Hospital for Nervous Diseases, Welbeck-street, W.—Hon. Asst. Surgeon.
Wigan, Royal Albert Edward Infirmary and Dispensary.—H.S. At rate of £150.
Willesden General Hospital, Harlesden-road, N.W.—Res. Officer. At rate of £100. Also Asst. Surg. O. £50.
Wokingham, Berks, Pinewood Sanatorium.—Asst. M.O. £550.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Dingwall (Ross) and Stapleford (Nottingham).

SWINDON VICTORIA HOSPITAL.—More beds are needed at this hospital, while there has been a large increase in the out-patients' department. An average of four beds has been occupied by road accidents, with an average stay of 15·8 days. The outlay for these cases has been considerable, and the full cost of treatment has rarely been recovered. There was an excess of income over expenditure of £13 owing to some substantial legacies and the contributory receipts were over £5000.

NOTES, COMMENTS, AND ABSTRACTS

OTO-RHINO-LARYNGOLOGICAL CLINICS IN BOSTON AND PHILADELPHIA

By Maxwell Ellis, M.D. Lond., F.R.C.S. Eng.
SENIOR REGISTRAR, GOLDEN SQUARE THROAT HOSPITAL

During my tenure of the Geoffrey E. Duveen Travelling Studentship I worked at the Massachusetts Eye and Ear Infirmary, Boston, from Feb. 1st to May 1st, 1934, and at the Chevalier Jackson Bronchoscopic Clinic, Philadelphia, for eight months in 1933 and 1934. I have set out below a brief account of these clinics for the benefit of those who have not had the privilege of visiting them.

The Massachusetts Eye and Ear Infirmary, Boston

In 1824 two Boston doctors started a free clinic for the treatment of diseases of the eye. This occupied only a single room, but was so successful that a fund was started and the money was raised to found the Boston Eye Infirmary in 1826. This grew rapidly, and in 1827 moved to larger quarters and was formally incorporated as the Massachusetts Charitable Eye and Ear Infirmary. The hospital continued to expand and was moved several times, until it arrived, in 1899, at its present site overlooking the Charles River. For many years the eye department was the more important one, but in 1922 the laryngological department of the Massachusetts General Hospital became an integral part of the infirmary, closely related with the ear department, and in 1925 the aural and laryngological surgeons appear in one group as "oto-laryngologists." In 1924 the name of the infirmary was changed by the omission of the word "charitable."

The building.—To-day the infirmary contains 250 beds, equally divided between the ophthalmologists and oto-laryngologists. The basement of the building is occupied by the kitchens, dining-rooms (for the nurses and house-officers), furnaces, and other domestic offices.

The ground floor contains a large laboratory, where the routine pathology and the research work connected with the oto-laryngology department is conducted. It can also be used as a lecture-room, and is equipped with projection cameras for lantern and microscope slides, moving pictures, and a special one for projecting X ray negatives, as well as an orthodiagraph. This laboratory was designed by Dr. H. P. Mosher, the chief of the staff, to fulfil these several functions, and has been furnished largely at his own expense, to include every device for photography and microphotography. The X ray department, the laboratory (with a specially endowed library) belonging to the ophthalmology department, and the various business offices occupy the remainder of the floor. The X ray department is well equipped, and has a large room for fluoroscopy, much used in the treatment of patients with œsophageal disease, and also in the endoscopic removal of certain radio-opaque foreign bodies.

The first floor consists of the male wards and the four operating theatres, equally divided between the two departments. The out-patient department, a very spacious and well-equipped one, is also on this level, in a special building devoted otherwise to the out-patient departments of the adjoining Massachusetts General Hospital. These three buildings, the two hospitals and the out-patient block between them, communicate with each other on every floor.

The third floor contains the female and children's wards, again equally divided; and the top floor consists entirely of single rooms for private patients, and an operating theatre, where all operations on private patients are performed.

There is a separate building adjacent to the infirmary, the lower half of which contains isolation wards for very septic cases or suspected cases of infectious fevers. The house-officers' quarters are in the upper half.

Private patients.—Connected by underground passages with the two hospitals already mentioned are two others for private patients, the Phillips' House, which is very luxurious, and the Baker Memorial Hospital, for persons of moderate means. All members of the staff have the privilege of sending their private patients to these hospitals.

Association with general hospital.—Thus, although the Massachusetts Eye and Ear Infirmary is an independent organisation as far as finance and policy are concerned, it is closely associated with the Massachusetts General Hospital (which can be regarded as the parent institution of the group) to the benefit of both. This association takes practical shape in the joint filing and keeping of records, and in the formation of various clinics, such as the tumour, allergy, and thoracic clinics, presided over by members of both hospitals. The nursing staff of the infirmary is supplied from the main hospital.

Charges made to patients.—Adult out-patients are charged seventy-five cents for the first visit and fifty cents for each subsequent visit. For children under 16 years of age, these figures are, respectively, fifty and twenty-five cents. In-patients pay what they can afford. All investigations, such as X ray and blood counts, are added to the cost borne by the patient, and a very efficient almoner's department takes care of this aspect of affairs. Many patients, however, are treated free.

Staffing.—So far the organisation will have been seen to differ little in essentials from that of our own hospitals. It is in the method of staffing where fundamental differences begin to appear. First of all there is a director of the whole hospital. He is always a doctor, is appointed by the board of trustees, and organises the medical and business administration. His influence is not always openly visible, but it is nevertheless constantly present. The post is now held by Dr. George H. Bigelow. Under him are two main executive officers, Dr. Frederick H. Verhoeff, the chief of ophthalmology, and Dr. Harris P. Mosher, the chief of oto-laryngology and professor of oto-laryngology in the Harvard medical school. Each is a virtual dictator in his own department, but answerable to the director and trustees. These three men are paid salaries, and do not engage in practice outside the infirmary. They have their private consulting-rooms in the infirmary, and are allowed to see a certain number of private patients—a nurse and a stenographer is provided for each of them. Appointments to the staff originate by recommendation from the board of surgeons, but the chiefs of staff and director wield considerable influence in this regard.

The oto-laryngology department is subdivided into otological and laryngological sections. There are three full surgeons to each section, and each takes his turn for four months at a time—this is known as being "on service." Thus each surgeon for eight months of the year has no hospital commitments as far as non-paying patients are concerned. He has an associate and an assistant surgeon, and several clinical assistants attached to his "service." The whole acts as a unit and deals with the out- and in-patient work of the public wards. This is known as the system of "rotating services," and is widely used in the United States. It gives opportunities to more younger men than our own system, and allows the older men with established practices a respite, other than their annual vacation, from hospital work. When not "on service," the staff members are privileged to use the private wards. The various "services" are welded into a homogeneous whole in the way I shall soon describe.

The X ray department is under the charge of an officer (Dr. A. S. Macmillan) who is paid a salary and attends at the infirmary every morning until lunch-time. The out-patient clinics take place, and all operations, except emergencies, are performed in the morning. Nearly every patient is X rayed for sinus, mastoid, or laryngeal disease. Nurses trained to the work take these films. The officer in charge attends regularly in the operating theatres, and with experience becomes skilful at correlating the information thus acquired with the X ray appearances. He personally conducts all the fluoroscopic examinations and gives a full report on each film.

All material removed at operation is sent down to the laboratory, and the sections prepared from it are reported upon by the assistant in the laboratory, in consultation with Dr. Tracy B. Mallory, the chief of the pathological department of the Massachusetts General Hospital. The assistant is not paid a salary, and usually occupies the post as a preliminary to becoming a house-officer.

Finance.—The infirmary depends financially upon its endowments, which are moderate, on fees paid by patients, which form the bulk of the income, and on voluntary contributions, a very variable factor. The patients pay more than they would in similar English institutions; on the other hand, much extra expenditure is involved in the salaries paid to the various members of the staff to ensure their full-time work.

TEACHING METHODS

Undergraduates.—Teaching methods employed by Dr. Mosher in the department of laryngology and otology may be of interest. The students in the Harvard medical school receive a course of lectures on the diseases of the ear, nose, and throat, and are made to practise with the head-mirror on specimens before doing so on patients. Many ingenious preparations have been devised for this purpose. For example, one consists of a head from a cadaver mounted in a wooden frame on which to practise indirect laryngoscopy and anterior rhinoscopy. Another is a half-head sectioned so that the ear drum is the dividing line between the superficial and deep portions. The drum is removed, and a small piece of paper with a printed representation of a drum is used to replace it. Paracentesis can conveniently be practised on such a model. Senior students are allowed to examine patients, and attendance at many demonstrations in the out-patient department is compulsory. As a result the average Harvard medical student has opportunity to acquire considerable technical skill in oto-rhino-laryngological examination. Certain members of each "service" are assigned for teaching in rotation.

The *post-graduate* course in rhinology and laryngology is given by Dr. Mosher. It is founded on two principles: (1) that a sound knowledge of anatomy and pathology is essential, and that this is likely to be lacking in men who have been engaged in practice for any length of time, which men form the bulk of the post-graduate students; (2) that anatomy can best be learnt by dissection, and pathology by the study of morbid specimens and slides. Thus a number of cadaver heads and half heads is issued to each man for dissection. He then draws his specimens (using a drawing-box) and makes plaster casts of certain of them. There can be little doubt that he will remember the anatomical features of a specimen which he has dissected, drawn, and cast in plaster and painted, and in any case he retains the cast as a reminder. It takes very little time to learn to produce an average cast though a really artistic one demands much skill. The whole head and neck, with the brain, is thus dissected, drawn, and modelled. In addition, there are lectures on anatomy, pathology, and neurology, and many slides are issued for study. Each man has to prepare a paper which he reads to the whole class, illustrating it with specimens or lantern slides. Regular viva voce examinations are held weekly. At the conclusion of the six weeks' course, each man has a number of plaster casts which he can take home to serve as a three-dimensional atlas.

Resident appointments.—As has been noted above, a man waiting for resident appointment can sometimes obtain a post as assistant in the laboratory, where he is trained in the technique of section-cutting, microphotography, and in histo-pathology and in methods of research. He also spends some time in the out-patient and X ray departments and learns enough about the technique of preparing plaster casts of dissections to demonstrate to post-graduates. About a year is thus spent in pathology as a preliminary to the 22 months as a resident. During this latter period, the house-officer spends three months in each of the various "services." His first three months are occupied with routine clinical pathology. All in-patients have blood counts performed on admission; the house-officer also examines all specimens of cerebro-spinal fluid, and is responsible for taking a full history of every patient on admission. His experience includes three months with the plastic surgeon (Dr. V. I. Kazanjian).

Consultations and discussions.—Every Wednesday morning at 11.30, a meeting of all members of the staff is held in the laboratory when microscope slides from recent cases are projected and described by the assistant, and any unusual cases of the week are presented by the residents. A free discussion follows. Once a month the meeting is devoted to cases which have proved fatal.

Other meetings are held on Friday evenings in the Harvard medical school, where an article of interest from the current journals is assigned to each house-officer, whose task is to present it in abstract, illustrating it as best he can with the material at hand, or making models and drawings himself. As his paper is open to discussion, he must also have familiarised himself with the bibliography given with the article, and with other work which this may not have included.

On Monday evenings, a selected member of the staff dines with the residents and afterwards gives an informal talk on a previously determined subject.

It will be seen that a young doctor who has spent three years at the Massachusetts Eye and Ear Infirmary will have received an excellent training in anatomy and pathology, will have seen a large amount of clinical work critically handled, will have had considerable operative experience, and will have learned how to present cases and papers before an expert audience.

The Chevalier Jackson Bronchoscopic Clinic, Philadelphia

In 1907 Dr. Chevalier Jackson published his first book on endoscopy, a prelude to a larger and more complete work which appeared in 1915. He built up his first bronchoscopic clinic in Pittsburgh, but came to Philadelphia in 1917 and set up a clinic at the Jefferson Hospital. Later on he developed two more at the Graduate and University hospitals, and in 1930 a third at Temple University Hospital, to which he now devotes his sole attention; over five thousand new cases from all over the world were dealt with at this clinic last year. His enthusiasm and inventive capacity remain unimpaired, and he is still in pursuit of the ideal of an endoscopic clinic with a trained personnel as part of the standard equipment of every large general hospital.

This clinic is situated in the northern part of the city, four miles from the centre. Dr. Jackson insists that all visiting assistants must stay at least three months and must live near the hospital, but this does not apply to members of the fortnight's course which is given twice a year.

Buildings.—The clinic occupies a suite of rooms on the second floor of the Temple University Hospital. These consist of Dr. Jackson's private office, a changing-room, the main office, an examining-room, a scrubbing-up-room, a preparation-room, and the operating theatre, with a stand for spectators. Each of these connected rooms opens also on to the passage.

Anæsthesia.—All patients, except children under 10 years of age, receive local anæsthesia (10 per cent. cocaine) before endoscopy. Out-patients who will be able to leave the hospital shortly after treatment, walk into the examining-room and are anæsthetised there. In-patients are brought up on carriages and wheeled into the preparation-room, where they are given their local anæsthesia.

The *personnel* of the clinic consists of Dr. Chevalier Jackson, the professor of bronchoscopy, his son, Dr. Chevalier L. Jackson, the professor of clinical bronchoscopy, Dr. E. Van Loon, the associate professor of bronchoscopy, and a clinical assistant, Dr. N. M. Levin. These three last-named are on salaries, and, with the exception of Dr. Van Loon, are full-time workers. The medical staff is completed by an unpaid assistant who stays for varying periods, not less than three months. This last post is generally filled for many months ahead.

The nursing staff consists of a head nurse and her assistant, both fully trained in the work, and a "pupil nurse," corresponding to a staff nurse in her last year of training. On operating days, another nurse is sent to the clinic. Each nurse has her own particular work in the team.

The *theatre* contains an operating table of the type designed by Dr. Jackson, a large cabinet draped with sterile sheets containing laryngoscopes, bronchoscopes, and œsophagoscopes, a movable stand for six dry-cell batteries, two electrically driven suction-pumps, and stands and tables for forceps, bougies, aspirators, swab-holders, sterile gowns, gloves, sheets, and head-holding towels; a set of instruments for tracheotomy is provided for emergencies.

Patients by appointment.—The clinic holds no out-patient department. All patients are referred by physicians from the various departments of the hospital or by outside doctors, and are given appointments. The secretaries who take a full history from each patient on arrival are not medically trained, but have acquired great skill in eliciting and setting out case-histories, and rarely omit anything of value.

Routine examination.—An ear, nose, and throat examination is made, and a thorough general examination, by the clinical assistant, the records being typewritten in triplicate. Then follow an X ray examination and a Wassermann reaction test. (All in-patients, by a Pennsylvania State law, have a blood count and an analysis of the urine performed on admission.) Cases of pulmonary disease and of suspicious tuberculous laryngeal disease have the sputum examined, if this has not already been done. Very often another physician is called into consultation, especially with children. No effort is spared to discover everything possible before an endoscopic examination is performed.

Types of cases and treatments.—The operating days are Mondays and Thursdays, and there is an average list of 25 patients. An average list (9/4/1934) of the tentative diagnoses of 27 cases is as follows: laryngeal stenosis, 5 cases; œsophageal stenosis, 5 cases; pulmonary abscess, 4 cases; bronchiectasis, 3 cases; papilloma of larynx, 2 cases; asthma, 2 cases; achalasia of the cardia, 1 case; cancer of the larynx, 1 case; "cough," 1 case; "dysphagia," 1 case; "hoarseness," 1 case.

For these patients the procedures adopted were: œsophagoscopy (7 cases); bronchoscopy (11 cases); direct laryngoscopy (9 cases).

Each doctor has his own patients, but occasionally a certain amount of interchanging takes place. Three doctors at least are essential in order to keep the list going without waiting between cases. One cocainises the patients in the preparation- or examining-room, while another holds the head for the operator.

Other treatments are carried on daily. These consist chiefly of dilatation of œsophageal stenoses by means of pneumatic dilators, retrograde bougies, or Hurst's mercury bougies. A certain number of patients come up for dressings. Each patient is given an appointment, so that, day by day, the work of the clinic follows definite and systematic lines.

Procedures other than endoscopic examinations are usually not undertaken on Mondays or Thursdays. All laryngeal operations except laryngectomies are performed by members of the clinic. Cases for laryngectomy, together with those for excision of a pharyngeal pouch (performed as a one-stage operation), are handed over to the senior surgeon, Dr. Wayne Babcock. In these latter cases, however, the endoscopist assists by passing an œsophagoscope into the pouch during the first part of the operation, and during the actual excision, reintroducing the œsophagoscope into the œsophagus to prevent removal of too much tissue with consequent stenosis. Gastrostomies are performed for the clinic by the general surgeons.

Foreign bodies.—All cases of foreign body, which form a little under 5 per cent. of the work of the clinic, undergo a searching clinical examination, and are then X rayed. The X ray department, under Dr. Edward Chamberlain, assisted by a large full-time staff, is magnificently equipped and renders invaluable information. The kind of foreign body, the length of time it has been present, and whether any previous attempts at removal have been made, are all taken into account in deciding when to operate. Removal in cases of small or peripherally situated radio-opaque pulmonary foreign bodies (and the rare cases of gastric foreign body) is performed under fluoroscopic guidance. To this end Dr. Chamberlain has designed a biplane fluoroscope embodying special features which lightens considerably the task of the endoscopist. It also affords the maximum of protection to the patient and bystanders. This apparatus is housed in a large room opposite the clinic, so that the pumps, batteries, and instrument table can easily be wheeled into it.

Teaching and research.—In the medical school another set of rooms is devoted to teaching and research. It contains four complete sets of instruments, operating tables for work on the cadaver and on dogs, numerous foreign bodies of all descriptions with which to practise, a lantern slide and a moving picture projector with a screen, numerous lantern slides and films, drawing paper, and chalks of a special make which Dr. Jackson uses effectively, and every conceivable device for endoscopic work and teaching. Every new assistant is given instruction here, first on the cadaver, and then on dogs, until his technique is considered sufficiently good for him to be allowed to work in the clinic itself. Dr. Jackson holds strongly that the education of the eye and the hand necessary for endoscopic work is best acquired by continual practice on the cadaver and on animals, and that the patient should not be the victim during the gaining of such skill.

It will be observed from the figures quoted above, of an average day's work, that although Dr. Jackson's interest in endoscopy was at first stimulated by the mechanical problems presented in the removal of foreign bodies from the bronchi and œsophagus, the clinic has long outgrown this limited sphere of usefulness. The clinic links up with nearly every other department of the hospital. Dr. Jackson believes that endoscopy has now reached the point where it should be regarded as one of the routine methods of clinical examination and treatment, and that medical students should be taught to consider it as such. This presupposes that the endoscopist has been thoroughly trained in general medicine and surgery as well as in direct endoscopy. In Philadelphia and also in other large American cities endoscopy is attaining this position in medical education and the supply of well-trained men is adequate.

In addition to cases with pulmonary and bronchial suppuration, many of which are given regularly recurring treatments, all cases of asthma are sent by the asthma clinic for bronchoscopy. It has been found that often an aspiration reduces the frequency the attacks, and that relief has followed the ministration of an autogenous vaccine prepared om the aspirated secretion. Especially in children th pulmonary suppuration of unknown origin, oncoscopy has frequently been of assistance, casionally revealing an unsuspected foreign body, helping, by regular aspirations, in the resolution the suppurative process. The chest physicians e sending more and more of their cases to the nic, as they realise how useful endoscopy may be them. In carcinoma of the bronchus the growth ten originates in the larger bronchi, within endoopic view, and the possibility of early diagnosis these days of rapidly improving technique in oracic surgery may be of great importance.

Patients with dysphagia form the great majority the œsophageal cases. The advantages of conntration of such cases are clear, especially for common diseases such as achalasia of the cardia non-malignant ulcerations or strictures at the ver end of the œsophagus.

The laryngeal cases are divisible into those with enosis, chiefly children, and those with benign owths or malignant disease. Persistent hoarseness is e symptom for which most of the patients are sent the clinic, and, owing to Dr. Jackson's insistence on endoscopy in all such cases, he sees probably higher percentage of cancer cases than any other yngologist in which the prognosis of laryngosure would be favourable. A large number of nign tumours of the cords are removed under rect vision, with complete relief of symptoms.

Gastroscopy is another growing aspect of the nic's activities, the Schindler flexible gastroscope ing used with satisfactory results in collaboration th the gastro-enterology department.

I have attempted to describe only the scope and me of the aims of the clinic, and have not entered o any discussion of the methods of treatment opted in particular diseases. These have all been blished by Dr. Jackson in a series of papers extendg over a period of nearly forty years and are miliar to all laryngologists.

In all the work of the clinic insistence is laid upon instaking preliminary investigation, gentleness of ocedure, and examination by direct vision whereer possible.

MEDICAL AUTHORS IN THE THIRTEENTH CENTURY

THE medical literature of six and seven hundred ars ago contemporary with the paramount activities the church was mainly in the hands of clerical gnatories, and in the current "Annals of Medical story" this is clearly shown by an essay on the edical writers of the thirteenth century in England itten by Dr. J. C. Russell. Medical literature in igland held a high position with such contributors as nong those mentioned by Dr. Russell), Gilbertus iglicus, Richard of Wendover, Roger of Lacock, igh of Evesham, and many others, whose names cur frequently in footnotes to historical articles d who come in here for reference. These writers, arly all of them, held clerical office, at any rate as acons, very usually as prebends or canons, or at ist enjoyed the profits of some clerical endowment, d there is one cardinal among them. Many of them, d most who attained to any stable repute, were, as ght be expected, general scholars, and their learned ormation with regard to medical matters was only cidental. The impression produced on Dr. Russell his studies, as it will be by those who read his say, is that these medical authors were a highly spected group, as often rewarded for other activities for any professional medical service. The documents of the time do not discriminate between the asters of medicine and the scholars whose chief im to recollection is their record of other activities an those of medicine, and often, as Dr. Russell ys, only chance mention enables the label of ysician to be affixed to their names. It is thus necessary for any who write on the general society of the thirteenth and fourteenth centuries to remember that the careers of those ancient writers cannot be used as typical of the general status of the medical profession of the day—they may have been as learned physicians as any of their time, for otherwise they would not have received the distinguished patronage of the Crown and the Church, but they dropped into medical authorship as incidentally as Silas Wegg dropped into verse. Actually their contributions to therapeutics in many cases remain unestablished, for it is clear from the copious references to their writings appended to Dr. Russell's essay that a great deal of work for the literary antiquarian remains to be done. Among these references the author of the famous work, "Rosa Medicinæ" apparently has escaped notice, but John of Gaddesden was of the epoch described, and has been credited by Norman Moore as suggesting Chaucer's "Doctour of Phisik." A delightful account of him was written some years ago by the late Dr. H. P. Cholmeley as a thesis for a doctorate.

SWISS MEDICAL YEAR-BOOK

THE *Schweizerisches Medizinisches Jahrbuch* for 1935 shows many improvements on earlier editions. It is because the country is small and compact that a medical survey can be so concise, but it is greatly to the credit of the editors, Dr. Felix Barth of Basle, Dr. Otto Leuch of Zurich, and Dr. (jur.) Hans Trüeb of Berne, that it should also be readable and attractive. The first hundred pages or so are taken up by a series of biographies and reviews, including a valuable conspectus of new drugs by P. Wolff of Geneva. Among the appendices are useful articles on the use of microscopic stains by the practitioner and on the removal of drug stains from fingers and clothes. The photographic illustrations of the various baths and health resorts are excellent. The Jahrbuch may be had from Benno Schwabe and Co., Basle, for nine Swiss francs.

LUIGI CORNARO[1]

Mr. George Cooke, in a preface of 31 pages, introduces us to an essay of 20 pages and 10 pages of mixed material consisting of a topical biographical note, some maxims on the prolongation of life by an unknown seventeenth century writer, and an essay by Addison extracted from *The Spectator*. The meat inside this considerable crust is an English translation of Luigi Cornaro's "Treatise on Temperance and Sobriety." In this work, which from internal evidence appears to have been written when the author was about eighty, the virtues of self-control life are set out, the conclusion being "that an orderly life is the most sure way and ground of health and long dayes, and the true and onely medicine of many diseases." Cornaro practised his rules of living with such success that he became a centenarian, and according to his grand-daughter, a Paduan nun, his mind did not decay, his sight and hearing were not affected, and, which is more difficult than the rest to believe, he sang at the end of his life "with as much strength and delight as he did at the age of 25 years." There seems insufficient material in the treatise to furnish ground for comparison of Cornaro's system of life with modern theories of diet, that being the task which Mr. George Cooke has set himself in the introduction, while the points which he puts out for the instruction of those who would enjoy a long and healthy life follow the teaching of many dietitians. His appreciation of the significance of figures may be judged by the fact that he does not seem to think an expectation of prolongation of life of about five years, as between 1871 and 1921, a considerable one.

ADDRESSES AND ORIGINAL ARTICLES

RESPIRATORY AND VASCULAR CHANGES IN THE MAMMAL BEFORE AND AFTER BIRTH *

BY SIR JOSEPH BARCROFT, C.B.E., F.R.S.
FELLOW OF KING'S COLLEGE, CAMBRIDGE, AND PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY

THE object of my lecture is to give you, in so far as I can, some consecutive idea of the respiratory and vascular changes which occur in the fœtus during birth. As a preliminary, therefore, I must say something about the life led by the fœtus; I must further make it clear that the information which I have been able to procure mostly from experiments on sheep has been elicited from Cæsarean sections.

Imagine then that there is in front of you a bath of such a size that it will contain the body of a sheep or goat, while the head projects from it and is supported by the back of the bath. The sheep is under an anæsthetic, which in most of my experiments has been urethane, but in some the animal has been rendered insensitive to pain by the injection of starch grains into the carotid artery—a procedure which was shown by Prof. Langley (1923) to be the equivalent of removal of the higher centres. The abdomen is in the bath and is immersed in saline solution; it is opened and the uterus exposed; the uterus is then opened and the fœtus withdrawn. The fœtus is now lying entirely immersed in saline at about 100° F., but with its circulation unimpaired and of course attached to the placenta by the cord. Perhaps the first thing which strikes you is that the fœtus is flaccid and movement only occasionally takes place, the second is the strength of the pulse in the cord, the pulsation being easily visible owing to the movement of the cord produced by each heart beat.

The strength of the circulation in the cord prompts the question: how much blood does the fœtal circulation contain? Another question follows closely upon the heels of that one: what proportion of the blood is in the fœtus and what proportion in the placenta?

Blood Volume

The fœtal blood volume has been fully investigated by Elliott, Hall, and Huggett (1934), who found that, relatively to the weight of the fœtus itself, the blood volume was very large in the early stages of fœtal life and, though increasing absolutely, its ratio to the fœtal weight became progressively smaller as time went on. At birth the fœtal circulation might contain for a kid of about 3 kilos. 500 c.cm. of blood. The gist then of the work of Elliott, Hall, and Huggett was that at birth the quantity of blood in the fœtal circulation, including the placenta, was about 15 per cent. of the weight of the fœtus, and that after birth the mass of circulating blood bore the same relation to the weight of the kid. If this be true one of two things must follow: (1) either the quantity of blood in the placenta and cord is negligible, or (2) the blood from the placenta is collected into the fœtus at birth.

In sheep I have made some observations to ascertain what proportion of the whole fœtal blood was actually in the fœtus and what proportion in the placenta and cord with the results shown in Table I.

We are left then with a picture of the fœtal circulation as divided into that of the fœtus itself and that of the cord and placenta. The former contains one-half to three-quarters of the blood, the latter from one-quarter to one-half. We have reason too to suppose that the blood from the placenta, or most of it, is withdrawn into the fœtus at birth. This point will arise later. The reason why the blood volume becomes proportionately smaller as the fœtus grows is that the fœtal circulation includes not only the fœtus itself but the fœtal vessels in the placenta. The placenta does not grow pari passu with the fœtus but before it, and therefore in the earlier stages of pregnancy the placental circulation forms a much greater proportion of the whole fœtal vascular bed than it does later on. It would be an exaggeration to say that a small fœtus consisted functionally principally of a heart which pumped blood through the placenta, but the exaggeration would be no greater than that legitimately allowed to the caricaturist who produces a more telling likeness than the realist.

TABLE I

Serial number of sheep.	Fœtal age in days. (Period of gestation about 150 days.)	Percentage of fœtal blood.	
		In fœtus.	In placenta and cord.
6	84	57	49
7	96	48	52
11	111	66	34
19	137	73	27

Blood Pressure

It is necessary to distinguish clearly between the quantity of blood which is actually in the placenta at a given time and the quantity which irrigates it. The former is the measure of the vascular bed for the time being, the latter depends not only upon the bed but also upon the pressure with which the blood is driven through the placenta, that is the pressure in the umbilical artery. This is probably not very different from that in the carotid artery, and therefore the data given in Table II. may be taken as typical.

TABLE II

Serial number of sheep.	Fœtal age in days.	Artery.	Pressure mm. Hg.
12	49	Umbilical.	20
50	101	Carotid.	34
39	120	,,	46
15	123	,,	50
19	137	,,	72
27	138	,,	68
28	140	,,	76

In the last six weeks or so of pregnancy the arterial pressure of the fœtal sheep more than doubles; this in itself will make a great difference to the amount of blood which circulates through the placenta. Yet even so, up to birth the fœtus is essentially an organism with a low arterial pressure; in the operation of birth the pressure rises by 20 mm. of mercury, so that in the newly born lamb it has a value of about 95–100 mm. of mercury. Could we reverse the process and go back from the lamb to the fœtus, we should say that the fœtus had gone into a state of collapse.

In this connexion, and perhaps at the risk of forestalling some points which must arise later, we can discuss the annexed tracing (Fig. 1). It reads from left to right;

---

* The John Mallet Purser memorial lecture, given at Trinity College, Dublin, on June 25th, 1935.

at the commencement it is a tracing of the arterial pressure of a sheep's fœtus approaching term, in fact 138 days old. At the end it is the blood-pressure tracing of a lamb newly born, and therefore the period which it covers, amounting to about five minutes, includes the whole operation of birth by Cæsarean section. I may justify the word birth by saying that the lamb lived a number of days in the laboratory fed by the bottle. At the commencement of the tracing the arterial pressure is about 63 mm. of mercury. At the point X the cord is tied; there is some rise of pressure which does not last, and the first breath (the breaths are indicated by arrows) took place 48 seconds after the cord was tied. Each breath is of the nature of a gasp or spasm, and is frequently associated with a general rise of blood pressure, but this rise of pressure is not maintained, and it is not till nearly five minutes after tying the cord that the organism can be considered as definitely launched; after that the blood pressure is maintained and the respirations become frequent and regular. Thus, remembering that in the last resort the two may be mutually dependent, we have separated the events of birth into two categories, the respiratory and the vascular.

The First Respiration

What is the cause of the first respiration? This takes place as the result of clamping the cord, but after a long delay. Three possible causes may be assigned as the one responsible for the first breath:—

(1) Oxygen want.
(2) CO_2 excess.
(3) Increased blood pressure in the brain.

The last seems an unlikely cause, but it demands more than a passing thought because, even before the first respiration, another phenomenon is apparent on the blood-pressure tracing—namely, a marked slowing of the heart. This is a feature, not only of fœtal asphyxia, but also of post-natal asphyxia and is attributed by Anrep's school to increased arterial pressure. But the first breath does not appear to be due to increased pressure, because it sometimes takes place in the absence of hypertension and sometimes as in the present case after the hypertension has passed off.

If excess of carbonic acid were the cause, it should be easy without occluding the cord to produce the breath by giving the mother mixtures of oxygen with large quantities of CO_2 to breathe. We have never been able to produce respiration in this way; indeed, the fœtus seems singularly unresponsive to CO_2 administered by this method.

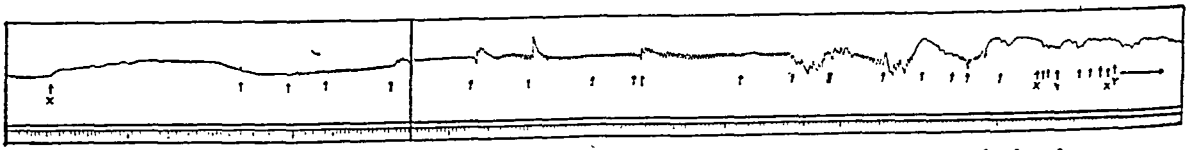

FIG. 1.—Tracing of the arterial pressure of a sheep's fœtus showing effect of tying the umbilical cord.

At X the cord is tied and at Y released. † = breaths. → = breathing continued regularly. The tracing is continuous except that, at the black line, one minute has been cut out in which nothing of moment happened.

That lack of oxygen may lead to respiration we have positive evidence.

(*a*) Other things being equal, the more blood the fœtus has in its body the greater will be its store of available oxygen and the longer should be the interval of time between occlusion of the cord and the first respiration. I have already shown that perhaps a quarter or a half of the blood is in the placental circulation. Advantage may be taken of this fact. If instead of pinching the whole cord the umbilical arteries only are pinched, leaving the umbilical veins free, the blood from the placenta, or a portion of it, should drain into the fœtus and in virtue of the oxygen which it contains postpone the first breath. This phenomenon can be produced with perfect regularity.

Fig. 2 shows three portions of the same tracing. In the uppermost (A), in which the whole cord was occluded, 41 seconds elapsed before the first breath took place; in the middle tracing (B), in which the arteries only were pinched, 57 seconds elapsed; while in the lowest one (C), in which the whole cord was blocked, 49 seconds elapsed. The middle tracing presents some points which indicate that blood from the placenta did actually find its way into the fœtus in quantity sufficient to affect the record. The immediate rise in fœtal arterial pressure consequent on the occlusion was much more marked and more sustained when the arteries only were occluded, and, a minute or so after the vessels were released, the middle tracing shows that the pressure became depressed to an extent which it did not in the first and last. Again, note that this depression was associated with intense slowing of the heart, which makes it difficult to argue that even the slowing of the heart was due to rise of blood pressure rather than to limitation of the oxygen supply of the brain.

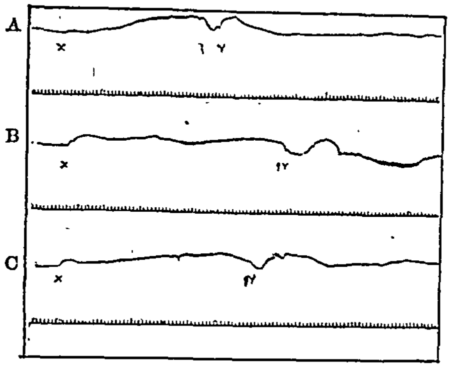

FIG. 2.—Three portions of a similar tracing showing effect of pinching—

(A) the whole cord, arteries, and veins,
(B) the arteries only,
(C) and subsequently the whole cord.
At X the vessels are pinched and at Y they are released.
† = breaths.

(*b*) If the first breath is due to want of oxygen, it would be satisfactory to produce the anoxæmia in some way which caused no upset to the circulation. Ordinarily such a method would be the administration of carbon monoxide: this standard method is not available in the present case because the carbon monoxide must needs be given to the mother and this, for several quite obvious reasons, would be unsuitable. We determined on the more heroic course of cutting down the oxygen content of the blood, by turning a portion of the fœtal hæmoglobin into methæmoglobin; this we did both by the injection of hydroxylamine chloride and of potassium ferricyanide, drugs which have little in common except their property of producing methæmoglobin.

Thus in a certain experiment (Sheep 39) in which the fœtus was quiescent but showed the usual phenomena on pinching of the cord, and in which pinching of one only of the two arteries failed to produce respiration, the injection into the umbilical vein of 65 mg. of hydroxylamine chloride in 2·5 c.cm. of saline produced respiration in 40 seconds. (Incidentally there was only a trifling rise in blood pressure and no slowing of the heart.) The effect passed off after a time, and a second injection was given which brought on respiration more rapidly and persistently.

Now it is clear that if this effect of hydroxylamine is due to the conversion of a portion of the fœtal hæmoglobin into methæmoglobin, the respiratory movements which it produces should be abolished by the injection of blood into the fœtal circulation. This in fact takes place. In the experiment just described, after the second injection of hydroxylamine had done its work and the respiratory movements had been established in a spasmodic way, 45 c.cm. of blood were transferred from the jugular vein of the mother to the fœtal circulation, with the result of immediately abolishing the spasms and bringing back the fœtus to approximately its original condition. And this alternation may be repeated. The proof, then, that the first respiration is due to depriving the fœtus brain of its oxygen-supply seems pretty clear.

I would enter one caveat here, and while I regard oxygen-want as the essential cause of the first breath, I am not prepared to say that the quantity of carbonic acid in the fœtal blood has no effect either in its magnitude or in the degree of oxygen-want necessary to cause it.

Before leaving the subject of the first breath let me say a word about its nature. I have spoken of it as a breath, but that quite inadequately describes it for it is a gasp, involving a great proportion of the muscles of the body. It may be questioned, indeed, whether the fact of air being introduced into the chest is much more than incidental. I mean that a general wave of contraction passes over a great part of the musculature of the body and since the diaphragm and intercostal muscles are powerful muscles the chest is opened. This gasp in fact seems to resemble in every possible way the dying gasp of an animal subjected to oxygen-want, say by cyanide poisoning or even deprivation of oxygen in the air; this is true in some detail, even to the order in which the muscles contract. From the point of view of the fœtus, the gasp is an index pointing, not to life, but to death, and we are faced with the remarkable paradox that the dying gasp of the fœtus is the earnest of life to the individual.

Slowing of the Heart

This remarkable phenomenon is so constant an effect of pinching the cord that it seems impossible to pass it over without taking a moment to consider its significance. When first I saw it, the idea struck me that it might have to do with the opening of the lung vessels that slow pulsations of large amplitude might, as it were, strike more effectively at the door and aid in opening up the vascular bed in the lungs more efficiently than would a rapid shallow pulse. That may or may not be so, but I do not think it is the important point.

Clearly there is hope for the fœtus to be born so long as the heart can beat. On what factors does the margin of time depend, between the cutting off of the placental supplies and the death of heart, in the event of birth not taking place? The heart presumably has at its disposal a certain amount of energy stored in some form or other, and can go on beating till this is exhausted. The energy which it uses in a given time is presumably a function of the initial tension at each beat multiplied by the number of beats; but in practice, as the initial tension does not vary very much, the energy at the disposal of the heart becomes exhausted proportionately to the number of beats which it gives. In other words, the heart can go into debt, oxygen debt or some other kind of debt, to the extent of a definite number of beats—say a thousand—so, clearly, the more slowly it beats consistently with preserving the blood pressure, the longer it postpones the inevitable end, should there be any difficulty in the establishment of the new respiratory and vascular conditions.

Course of Fœtal Circulation

One of the most obvious differences between the fœtus and the mother is that the former derives its oxygen from the placenta and the latter from the lungs. This change involves a fundamental alteration in the circulation. In the fœtus the blood which arrives at the heart may be divided into two categories. One portion comes along the inferior vena cava and consists of blood from the placenta and the lower part of the body. The second portion consists of blood coming from the head, the arms, the upper part of the trunk, and the coronary system. Let us first make an effort to discover what is the total volume of blood which passes through the fœtal heart per minute, and then we will pass to the consideration of the proportions in which these two main sources contribute to the whole.

The quantity of blood which passes through the fœtal heart per minute can be measured by a plethysmographic method. The great dangers of such a method are two: the first is lest it should give an incorrect measurement of the quantity of blood actually traversing the heart; the second, and perhaps the greatest, is lest the plethysmograph should restrict the blood flow. The present method was therefore calibrated in small animals against the blood flow as measured in other ways, and appears to give results too low by about 15 per cent. In calculating, the addition of 15 per cent. has been made to the figures as measured. The measurements gave singularly uniform results—namely, that, from the earliest date at which they were obtained until term, the volume of blood which traverses the heart is 0·15 c.cm.±0·03 of blood per minute for each gramme of the body-weight of the fœtus. These results were obtained in goats. They tend rather to increase as the fœtus grows older, but not outside the limits stated. It will be asked: how does this value compare with the quantity of blood which goes through the heart after birth? In fact the two are about the same. In making this statement I mean that the quantity of blood which traverses the fœtal heart is the same as that which traverses both ventricles after birth, and is therefore the double of what is ordinarily known as the minute volume—i.e., the volume of blood driven round the body per minute.

As regards the course of the stream, the information at our disposal comes chiefly from the researches of the anatomists. The classical picture they give is of relatively red blood arriving at the heart via the inferior vena cava, crossing directly through the foramen ovale to the left auricle, passing thence to the left ventricle, and so along the aortic arch and carotid arteries to the head. The dark blood from the jugular vein, brachial veins, azygos vein, coronary veins, &c., goes through the right auricle to the right ventricle and so along the pulmonary artery; such of it as gets to the body passes along the ductus arteriosus arriving in the aorta distally to the exit of the redder blood which goes to the coronary system, the head, the arms, &c.

It was naturally a matter of some interest to me to test the truth of the deductions made from an inspection of structure. The oxygen present in the blood at various fœtal ages and in various localities can be tested—not only so, but by studying both the composition of the confluents which form a given stream and that of the stream itself, the proportions in which the confluents mix can be determined. It is not necessary here to give all the details; summarised they amount to this:—

(1) The blood which passes through the heart may be regarded as forming two streams approximately equal in volume.

(2) One of these goes to the "head" and is not much inferior in its oxygen content to the redder blood which reaches the heart—namely, that coming along the inferior vena cava.

(3) The second, which is not much redder than the venous blood from the "head," goes to the "body," which means the lower part of the trunk and the placenta.

(4) Of the blood going to the "body," about two-thirds goes to the placenta.

The crossing therefore is nearly complete, almost every corpuscle which arrives from the placenta at the heart goes thence to the upper circulation, unloads oxygen in the head, the heart, the arms, &c., and then, traversing the heart again, goes up the ductus arteriosus and either unloads more oxygen, in fact most of its residual oxygen, in the body or goes to the placenta, there to receive another load.

This picture warrants a moment's thought, for, while it justifies the anatomical description, it seems to carry with it some implications which are not very easy. In the first place, on this showing, three times as much blood goes to the "head" as to the body. Can this be so? In order to find out the limits of the localities to which blood could go without passing down the abdominal aorta, the aorta was ligatured in fœtal guinea-pigs just proximally to the entry of the ductus arteriosus, a cannula was inserted into the left ventricle which was still beating and blue fluid was injected. As well as the actual head and arms, the whole of the chest wall was injected, and, what was very interesting, the coverings of the spinal cord down almost to the lumbar swelling. Thus all the organs which at this stage of fœtal life are functionally important, except the liver and the lowest section of the cord, can receive reddish blood from the upper circulation.

Now a word about the liver. It occupies a most remarkable place in the circulation which is very little stressed. The liver receives blood direct from the placenta—the purest which any organ receives—and therefore has a first option on whatever comes. In some animals, indeed—e.g., the horse, which is described as having no ductus venosus—the whole of the blood arriving from the placenta is poured into the portal vein and must traverse the capillaries of the liver before reaching the fœtal heart. Thus the liver of the fœtus is in as strong a position as that of the normal animal to receive and deal with everything that is necessary for the metabolic activity of the animal, all the products of absorption of foodstuffs as they diffuse through the placenta, as well as the necessary oxygen.

These considerations still further reduce the number of the important organs which are supplied with what may be called second-hand blood.

The Ductus Arteriosus

Another implication is as follows: if something like a third to a half of the blood leaving the heart traverses the ductus arteriosus, that vessel is one of the main arteries of the body and is in no sense an accessory or vestigial structure. Is it large enough to discharge this responsibility? If the ductus arteriosus is only capable of allowing the passage of 10 or 20 c.cm. of blood per minute, the picture which I have drawn is clearly an impossible one. Perfusion of the ductus arteriosus, however, shows that even in the cold and dead condition, when perfused at the pressure of the pulmonary artery, something like 120 c.cm. of blood per minute can pass along it. This is not quite the requisite amount, but it is of the right order.

I used the phrase "the pressure in the pulmonary artery." Here again is an implication, that the pressure on the right side of the fœtal heart must be much the same as on the left—namely, about 70 mm. Hg towards the end of fœtal life. Certainly the structure of the heart is not inconsistent with this conception, for at birth the thickness of the ventricle wall is approximately the same on the right and left sides. Therefore while the endocardiac pressure on the left side of the heart increases after birth that on the right side falls away to about 18 or 20 mm. of mercury—one-quarter of its fœtal value.

Here, however, is a more difficult question; if the efficiency of the fœtal circulation depends so completely upon the passage of a large quantity of blood along the ductus arteriosus, and the efficiency of the circulation after birth depends so completely upon the occlusion of the ductus arteriosus, it is rather difficult to visualise this closing as anything but a sudden process, either mechanical, such as a valve, or functional, such as a muscular spasm.

In this connexion the structure of the ductus arteriosus is interesting. It seems singular that its histology should differ materially from that of the arteries to which it is attached, yet that is the fact, for while the pulmonary artery and the aorta are highly elastic at birth, the ductus arteriosus resembles a small peripheral artery in its structure. The elastic elements are proportionately much less conspicuous and the muscular elements—or what seem to be muscular elements—are much more conspicuous than in the aorta or pulmonary artery. For the present, the closure of the ductus arteriosus must be left for further investigations which we have undertaken.

Respiration Before and After Birth

Without going into a detailed description of the events which take place in the placenta, suffice it to say that the oxygen passes from the maternal to the fœtal blood, so far as is known, by a process of diffusion. This process is greatly facilitated by the fact that fœtal blood has a considerably greater affinity for oxygen than the maternal blood. There are numerous ways in which such a result might be brought about. Perhaps the most obvious would be if the hydrogen-ion concentrations of the two bloods were different, and indeed it is true that the maternal blood during pregnancy is less alkaline than usual, a fact which tends to expel the oxygen from the hæmoglobin of the mother. But it is of the essence of the membrane which separates the blood of the mother from that of the fœtus that it should admit of the freest possible diffusion and therefore it cannot support any great difference of hydrogen-ion concentration on its two sides. It seems that the fœtus possesses a hæmoglobin of a different type from that of the mother, a hæmoglobin with a higher affinity for oxygen; this is true of the goat, the sheep, and the rabbit. The hæmoglobin of the chick also has a greater affinity for oxygen than that of the hen, and I believe even the tadpole's blood pigment differs in a similar way from that of the frog (Barcroft, J., 1935). Man at first sight presents the solitary exception, for the hæmoglobin of the human fœtus and even of the new-born child has a less affinity for oxygen than that of its mother, but this anomaly is set right when the hæmoglobin is not in solution but in corpuscles. We do not know what the essential difference between the pigment inside and outside the corpuscle may be, but, whatever it is, the effect of packing the hæmoglobin into the corpuscles is such that the pigment of the mother loses its affinity for oxygen to a much greater extent than that of the fœtus, and thus it happens that in the same buffer solution and at the same temperature the fœtal corpuscles in man, as in other forms, have a greater affinity for oxygen than those of the mother.

The relevant question is: at what stage does the fœtal hæmoglobin disappear and the post-natal hæmoglobin take its place? In the sheep this is almost exactly at birth. Up to the 138th day of fœtal life at all events there is no perceptible change. By the time the lamb is 39 days old the change appears to be complete, and even five days after birth it has gone a long way. Perhaps, however, the most remarkable thing about the transition is its nature. The affinity for oxygen is of course expressed by the oxygen dissociation curve, and it might be supposed that, given the pre-natal and post-natal types, the transitional type would lie between them so that it would be possible by mixing X c.cm. of typically embryonic blood with Y c.cm. of typically post-natal blood to get a blood the hæmoglobin of which gave an intermediate curve. This is not what takes place; the dissociation curve of the hæmoglobin derived from the blood at birth has a curve which is less inflected than that of either the pre-natal hæmoglobin or the post-natal hæmoglobin. Here again the chemical significance is not discovered. On the whole it looks as though the most likely explanation were not the right one and that the pre-natal pigment broke down in some way and was re-formed into the post-natal type.

From the point of view of function it must be borne in mind that, if the fœtal hæmoglobin has a greater affinity for oxygen than the post-natal type and so picks up the gas with ease in the placenta, reciprocally it gives up its oxygen with corresponding difficulty in the tissues. Is there any danger of the fœtus being asphyxiated because the hæmoglobin will not part sufficiently readily with its oxygen? This brings us to the question: does the fœtus use as much oxygen per gramme of tissue as the born animal? The coefficient of oxidation—to use the phrase invented by Chauveau and Kaufmann (1887) to express the number of cubic centimetres of oxygen used per gramme per minute—is known pretty accurately for goats at rest to be on the average 0·0085 c.cm. For kids in the first three days of life we have made a number of observations which varied from 0·005 c.cm. in a kid of 20 hours which had not been fed to 0·01 c.cm. ± 0·001 during the first week of life. This figure is in contrast to the metabolism of the fœtus. This is not easy to measure, and any measurement depends upon certain assumptions. The determination was first made by Zuntz and Cohnstein (1884), who did experiments upon sheep with results which varied greatly; their highest was 0·0025 c.cm. per gramme per minute.

We have done six experiments on goats and about the same number on sheep, and considering the difficulty of the task the results have come out with remarkable similarity. In the goat fœtus the coefficient of oxidation appears to be 0·0025 c.cm. ± 0·001. On the whole, as the embryonic age progresses there is a tendency for the coefficient to rise, but this is scarcely outside the region of experimental error. Then there is a great rise at birth. The kid a day or two old uses perhaps four times the amount of oxygen which it did when it was in the womb. The same appears to be true of the sheep. The conditions in the sheep fœtus seem so uniform that it is possible by a very simple calculation to arrive at the coefficient of oxidation. If the oxygen in the blood going to the placenta be subtracted from that in the blood emerging along the umbilical vein, and the figure so obtained—namely, the oxygen difference—be multiplied by the blood flow through the placenta, we shall get the coefficient of oxidation. Now we have already obtained a figure for the blood flow, by implication at all events. We have taken the blood flow through the heart as being 0·15 c.cm. per gramme of fœtus per minute, and we have taken the blood flow through the placenta as being the third of this—namely, 0·05 c.cm. per gramme per minute. Therefore the oxygen used per gramme per minute should be 0·05 c.cm., multiplied by the oxygen difference in c.cm. of oxygen per cubic centimetre of blood (Table III.).

TABLE III

Serial number of sheep.	Fœtal age in days.	Cubic centimetres of oxygen in 1 c.cm. of blood.			Oxidation coefficient of fœtus.
		Umbilical.		Difference.	
		Vein.	Artery.		
2	58	0·078	0·028	0·050	0·0025
8	98	0·088	0·048	0·040	0·0020
11	111	0·113	0·069	0·044	0·0022
14	112	0·157	0·104	0·053	0·0027
16	124	0·174	0·052	0·122	0·0061
19	137	0·068	0·017	0·051	0·0026
27	138	0·105	0·059	0·046	0·0023
29	144	0·102	0·038	0·064	0·0032

These results are (with one exception) practically the same as those of the goat, and as they too are very much less than the oxidation coefficient of the lamb we may take it that at birth there is a great increase in the quantity of oxygen consumed. Nor is this the whole story, for the vascular system of the born animal is made not merely to meet its requirements when at rest but to meet them when the organism is in the maximum condition of activity which it can sustain. This is true of the hæmoglobin no less than of any other feature of the vascular system. Therefore the hæmoglobin must in the active organism be able to unload its oxygen when the body is using oxygen not at the rate of 0·01 c.cm. per gramme per minute, but at perhaps ten times that rate.

But to continue the comparison between the organism before and after birth, in respect of the amount of oxygen which it requires, even the so-called resting kid or lamb is not at rest in the sense in which the word "rest" may legitimately be used of the fœtus. The greater part of the oxygen used by the body is used by its muscles; these are always in a state of tone. It used to be argued that muscular tone did not involve any extra use of oxygen and the so-called catch mechanism was invoked in support of this thesis. The new methods of amplification used by Adrian and others have shown that the true nature of tone in skeletal muscle is the contraction of a limited number of muscle-fibres in a given time. Tone must therefore be associated with oxygen use.

My colleague Dr. D. H. Barron has tested, at several periods of fœtal life, the question of whether the skeletal muscles of the fœtus are in a state of tone, and the result has always been the same—namely, that the muscles are perfectly flaccid so long as the fœtus is in its normal environment or in something approximating to it. Nor is there the same reason for the maintenance of tone in the fœtus that there is after birth. Once the animal is born, it is of the first importance that its body temperature should be maintained. This can only be done by oxidation, and even should tone develop into shivering the effort will be made. The fœtus, however, has no cooling surface of its own, and its presence does not greatly increase that of its mother, but in so far as it does, doubtless the maternal thermotaxic centre is equal to dealing with the situation.

The cogency of what has just been said has been proved by Barron in the following way: in warm saline and with the circulation unrestricted the fœtal muscles are, as I have said, devoid of tone. Take the fœtus out of the saline and expose its skin to the air; tone at once appears in its muscles, only again to be abolished by replacing the embryo in the saline.

COMBINED DISTANCE RADIATION OF HYPOPHARYNGEAL CANCER

By Stanford Cade, F.R.C.S. Eng.
SURGEON TO OUT-PATIENTS, WESTMINSTER HOSPITAL; AND
F. M. Allchin, M.B. Lond., D.M.R.E.
X RAY THERAPEUTIST TO THE HOSPITAL

The treatment of malignant disease of the region of the hypopharynx presents many difficulties. Surgical treatment has been placed on its present high level by the methods originated by Wilfred Trotter which remain the best that surgery can offer. They are limited however in their application to a small minority of cases, where the lesion is confined within the pharyngeal wall and the glandular involvement is limited. Even in such cases surgery is not always acceptable to the patient and the risks are grave in the most skilled hands. Some cases cannot be relieved without sacrifice of the larynx, and this grave mutilation is shown in its true light by Trotter's words: "I should not feel able to record as a true success the cure of a pharyngeal carcinoma won at he expense of laryngectomy." It is therefore natural that radiological methods should be tried out in this group of neoplasms. The outstanding advances in the radiological treatment can be summarised by the work of Coutard in France, Finzi and Levitt in this country, Zuppinger and his assistants in Switzerland, and the workers of the Memorial Hospital, New York, including Quick, Duffy, and Martin. As regards radium, the methods of interstitial and surface therapy have added very little to the practical treatment of these lesions; it is only when we come to mass radiation by large quantities of radium that improvements in results are recorded. In the radium treatment of cancer of the mouth, larynx, and pharynx by distance radium radiation, Berven stands alone as the pioneer of the treatment.

Our contribution to the treatment of cancer of the hypopharynx deals with a method of therapy which can be appropriately described as the "combined distance radiation." This combination of X and gamma radiation is applicable to most neoplasms, but at present we are only concerned with a group of tumours known to the clinician as "extrinsic laryngeal cancer," and including the hypopharynx. For radiological treatment as much as for surgical excision, correct diagnosis, accurate localisation, and careful grading or grouping of the lesions is essential.

FOUR ANATOMICAL GROUPS

The anatomical classification of the cases under consideration comprises the following four groups, which present different clinical features and require different techniques of treatment.

1. *Epipharyngeal Tumours.*—These are the true extrinsic laryngeal growths, originating in the aryepiglottic fold, epiglottis, or arytenoid. They give rise to early loss or modification of the voice and should be recognised with ease.

2. *Tumours of the Posterior or Lateral Pharyngeal Wall.*—In this group of cases the growth originates well away from the arytenoids, its possible level extends from the region of the uvula above to the post-cricoid area below; it may be confined to the posterior wall only or encroach on one or both lateral walls, or it may originate on the lateral wall. It extends inwards and may overhang the arytenoids and vocal cords, which, however, remain freely mobile.

3. *Pyriform Fossa Tumours.*—These constitute by far the commonest group. Early diagnosis is quite exceptional; glandular involvement is the rule and may at times be the first abnormality noticed by the patient. The mortality of this group is so high and operability so low that any other method capable of dealing with the disease must be seriously considered.

4. *Post-cricoid Carcinoma,* characterised by early dysphagia, the preponderance amongst women and the few signs visible on indirect examination in early cases. For such cases valuable diagnostic help can be obtained from careful skiagrams of the neck. The characteristic appearance is the displacement forward of the larynx and trachea and the ovoid shadow of the tumour prevertebral in position (Fig. 1).

In the clinical diagnosis of these cases we have had the advantage of the coöperation of a large number of laryngologists and we take this opportunity of expressing our thanks to them. The cases referred for treatment were seen and diagnosed by one or other of the following laryngologists: Mr. Gilbert Chubb, Mr. Douglas Harmer, Mr. F. C. Ormerod, Mr. W. Ibbotson, Mr. G. A. Simpson, Mr. N. A. Jory, Mr. Gill-Carey, Mr. N. Asherson, and Mr. E. Carew-Shaw. Our cases therefore were drawn from various hospitals, including Westminster, St. Bartholomew's, Mount Vernon, Ear, Nose and Throat Hospital, Golden-square, Central London Ear, Nose and Throat Hospital, and the Bolingbroke Hospital. Clinical diagnosis was always confirmed by more than one observer; in the majority of cases a biopsy and histological confirmation of malignancy preceded treatment.

HISTOLOGY

The histological classification of the tumours of the upper air and food passages varies from country to country; grading is somewhat arbitrary, and the following three groups cover the various types met:

(1) Squamous-celled carcinoma (with cell-nests).
(2) Transitional-celled carcinoma (without cell-nests).
(3) Lympho-epithelioma.

These three entirely different histological varieties of epithelial cancer may represent three phases of biological activity, the practical importance lies in the different life-histories of the three groups and their different degrees of radiosensitivity. Correlation between histological grouping and radiosensitivity showed that whereas lympho-epithelioma is always highly radiosensitive, the epidermoid type varies in its response and some squamous-celled tumours with cell-nests prove as sensitive as the more undifferentiated types. The gross physical characteristics of the lesion are as good if not a better guide to sensitivity than the microscopical grading. The cauliflower exuberant lesion responds better than the ulcerative infiltrating or nodular type, in accordance with the general rule. Sepsis, necrosis of tumours, or œdema militate against successful radiotherapy. Post-operative or post-radiation failures were not excluded from the series of cases treated by the combined method.

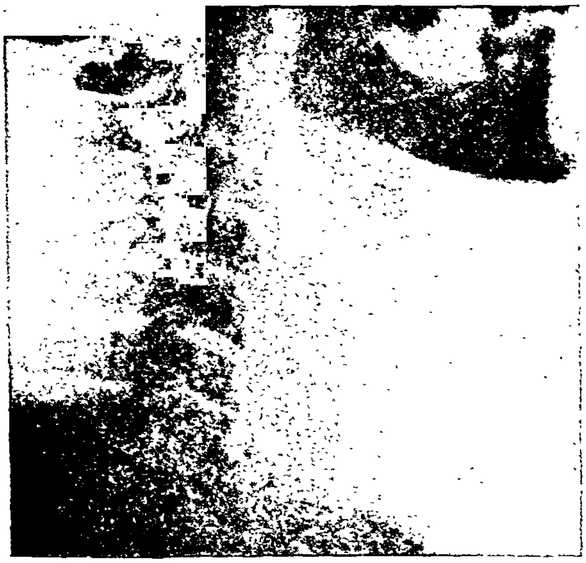

FIG. 1.—Skiagram of neck showing post-cricoid tumour and forward displacement of trachea. Note the distance between trachea and vertebral column; this is typical of the lesion.

TREATMENT

All patients were examined by indirect laryngoscopy; the situation, extent, and type of lesion were determined; oral hygiene and dental treatment precedes active irradiation. Skiagrams of the chest, neck, and a barium swallow are carried out; full blood counts are done weekly. The skin of the neck and the mucous membrane of the mouth are inspected daily, a complete laryngological examination is done weekly or twice weekly; in some cases daily. About one-third of the total number of patients treated are not hospitalised.

The method of treatment consists in a combination of radiation in the following order:

(1) Preliminary X radiation for 5 days.
(2) Simultaneous X and gamma radiation.
(3) Gamma radiation with the 2-gramme radium unit continued after cessation of X rays.

The use of radium and X rays in combination is not a new development. It has been used in many regions of the body, chiefly, however, by the method of needling with X rays as a preliminary or subsequent procedure. In America X rays have been used for several years in combination with the radium pack. Levitt, in 1930, stated that in the cases in which planned combined treatment was carried out, the results appear to be distinctly better than those treated by X rays alone. In many of these cases, he said, adequate treatment by radium alone would have been impossible in the first instance. In the treatment of the tongue, tonsil, and vallecula, he says also, that, where practicable, radium should always be combined with X rays. As far as we are aware, X rays had not been used in this country in combination with beam radium therapy previous to 1930, when the earliest cases were treated at Westminster Hospital. Since that date we have employed the combined method in many regions of the body, and in very varied types of malignant disease.

The remarks made by Quick at the International Conference on Cancer held in London in 1928 suggested a possible new method of attack on the malignant process. In speaking of the use of the 4-gramme radium pack and X rays, Quick says:

> "Our clinical observations were to the effect, that the practical results produced were superior to those where radiation of one wave-length only was used. We noted, furthermore, that bearing in mind the quantitative factor a relatively greater quantity of the combined radiation *within the limits of skin tolerance* could be given within a fixed interval than was possible where radiation of only one type was used."

Having at our disposal a constant potential X ray apparatus capable of giving 200 kilo-volts and a 1-gramme radium unit (afterwards increased to 2 grammes), we felt that this was an opportunity to test the method on carcinoma of the upper air passages. The rationale underlying the combined method is based on the following observations:

1. It was pointed out by Douglas Quick that a larger tissue dose can be given with safety and comfort by the combined method than by either method alone. If the total maximum dose given by each method alone is represented by 100 per cent., allowing a reduction of 25 per cent. for each type, a total dose of 150 per cent. can be delivered by the combined method.
2. It appears from observation of the cases treated that a variation of the wave length used increases the degree of radiosensitivity.
3. The local tolerance of the skin and mucous membrane is increased.
4. The limit of general tolerance of the patient is never reached before the limit of the local tolerance of the skin or mucous membrane, so that treatment need not be interrupted before an adequate dose is delivered.

TECHNIQUE: RADIUM

The bomb used is the fifth model constructed for Westminster Hospital (Fig. 2). It is of small dimensions, ovoid in shape, consisting of a spherical upper portion made of lead and a lower part cone-shaped made of gold. Its weight is 38 lb.; the external diameter is 14 cm., the internal diameter of the radiation channel is 3·5 cm.; the gold mouth is 1 cm. thick and 3 cm. long. The bomb is suspended over a pulley and counterpoised with a block of lead. It is easy to handle and stays in the position in which it is placed. A cone-shaped metal holder, the exact replica of the bomb, is accurately placed in position over the port of entry to be treated and fastened by rubber bands (Fig. 3). This is done outside the bomb room; the patient then comes into the treatment room, is placed on a couch which is swung into position under the bomb, and the attendant lowers the bomb into the cup; the bomb is attached to the cup in a few seconds. The radium contained in the bomb at present is 2 grammes in 9 tubes. The radium skin distance can be varied at will up to 7 cm.

Multiple small ports of entry are used. The number of ports varies with the situation and extent of the lesion and the presence of glandular metastases. Pyriform fossa lesions and lateral pharyngeal lesions are treated through 4 or 5 ports on one side of the neck; aryepiglottidean lesions through 3 ports on one side (Fig. 4) and postcricoid tumours through 2 ports one on each side of the neck; recently a third anterior central port has been added. The radium skin distance was originally 3 cm. but was gradually increased so that to-day 6 or 7 cm. radium skin distance is used in most cases. Each patient is treated 5 days a week and receives 2 treatments of 50 minutes each in the 24 hours. Occasional periods of rest, variation in the frequency of the treatments, and changes in the ports are dictated by the reaction of the skin and mucosa and by the response to treatment. The total period of treatment, including rests, extends over 6 to 7 weeks.

TECHNIQUE: X RAYS

A constant potential stabilovolt generator is used actuating a Siemen's multix 190 K.V. tube. Our kilovoltage has been 180 throughout. Filtration used 1·5 mm. copper + 1 mm. aluminium, except in the very early cases, when only 0·5 mm. copper was used. Lately a Thoraeus filter, which is equivalent to the 1·5 mm. copper, but which gives a more homogeneous beam, has been used. Focus: skin distance used is 45 cm. and at times 50 cm., and the size of the fields varies from 80 to 150 square centimetres.

As the metastatic spread is via the lymphatics, it seems to us that as widespread irradiation as possible consistent with safety should be used. Unlike Dr. Coutard and Dr. Hayes Martin, any ill-effects from the use of the larger fields have not been noticed, but this is most likely because the daily doses are smaller. Daily doses of from 120–180 r. units are given for five days a week, thus allowing two complete days rest in every seven.

Several minor variations to the main plan of treatment have been tried but the routine now is for the X radiation to precede the bomb on the affected side, or if the growth should be centrally situated or extend to both sides, for the X rays to be given to both sides before starting the gamma radiation. The bomb is then started and the X rays carried on with on the opposite side to the lesion and often from a posterior field in addition. This in many cases means that the X radiation is finished before the gamma.

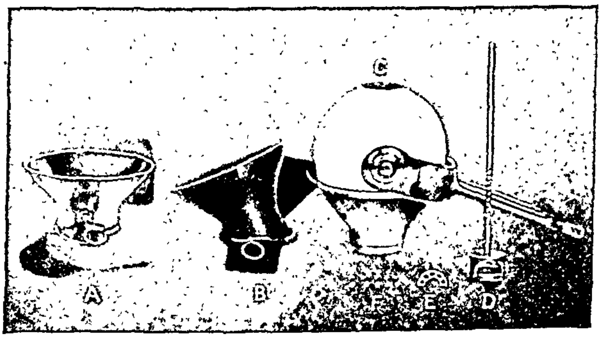

FIG. 2.—Components of the Westminster bomb. A and B metal cups, applied to patient outside bomb room. C bomb: upper part in lead, lower containing gold screen. D radium carrier, inside the bomb. E horse-shoe shaped container for five units of radium; this is inserted into D. F radium units, placed into E.

EFFECTS OF TREATMENT

(1) *Reaction of the skin.*—With increased radium skin distance, the cutaneous reaction has diminished in degree to a very appreciable extent. It is now possible to avoid moist peeling of the skin (Regaud's selective radio-epitheliitis). The appearance of erythema varies in individual patients; at 6 cm. distance, 10 hours' treatment can be given to each port before the erythema occurs. Dry peeling, pigmentation, and crusting are obtained towards the end of the treatment. It must, however, be emphasised that it is the mucosal reaction and not the skin reaction which is the determining factor of dosage, and treatment must be continued if other conditions dictate it, till full peeling of the skin is obtained. If blistering and peeling take place, healing follows in 10 to 14 days.

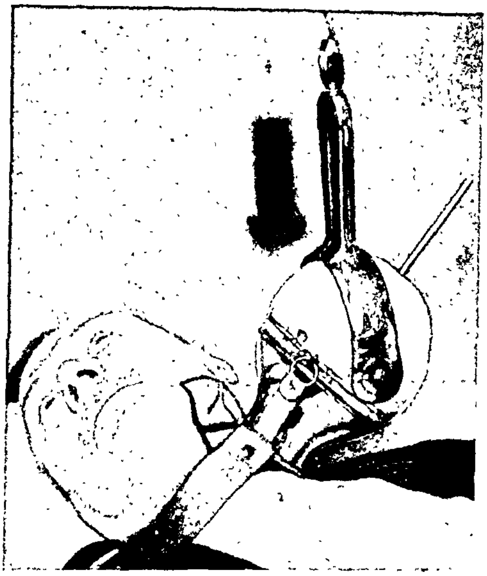

FIG. 3.—The bomb in position.

(2) *Reaction of the mucosa.*—Œdema of the mucous membrane, specially œdema of the arytenoids, is an early reaction; it occurs on the 3rd or 4th day, is transient, and gives rise to slight discomfort; towards the end of the treatment, œdema recurs and must be carefully watched; as a result of the treatment there is redness and dryness of the mucous membrane; occasionally a mild fungus infection of the palate and fauces occurs—this is an indication for interruption of treatment which can be resumed within a few days. *In two cases only,* both very advanced, was tracheotomy required in the middle of the treatment; in one case tracheotomy became necessary five weeks after cessation of treatment.

(3) *Perichondritis.*—No damage to the cartilages of the larynx or trachea has been observed so far up to periods of 3½ to 4 years after treatment. As this sequela is possible however as long as 7 or 8 years after cessation of treatment it cannot be excluded to date.

(4) *Blood changes.*—There is a progressive fall of leucocytes with *a greater relative* fall of lymphocytes throughout the treatment in the great majority of patients but not in all. The maximum fall is to 2000 total leucocytes and 250 lymphocytes. These changes are transitory, rapid recovery taking place during the periods of rest and on cessation of treatment.

General symptoms of radiation sickness are entirely absent.

CLINICAL COURSE

General constitutional disturbances have been very few and slight. A certain amount of depression, which is a very common feature, and loss of appetite, are the worst. We must remember as always that it is the patient we are treating and not alone the disease. This often necessitates modification of treatment, which would not otherwise be carried out. All factors relating to the general condition and habits of the patient must be considered. Whenever possible, cases are best treated as in-patients, thus avoiding daily journeys and fatigue, with risk of exposure to cold and infection. But neither the local reactions nor the effect on the general health are such as to preclude out-patient treatment throughout if the patient desires it. Smoking should be reduced to a minimum, or given up entirely where possible, but if this would militate against the patient's outlook, we prefer to let him continue. One inveterate smoker (as well as alcoholic) was treated with good palliative results, and lived in comfort for 16 months without renouncing either of his habits.

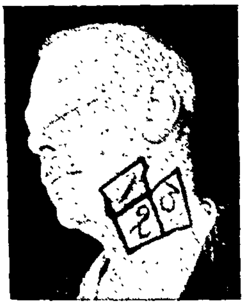

FIG. 4.—Ports of entry mapped out with Finzi's ink.

Frequent examination of the skin and mucous membranes is important, their exact condition being noted from week to week, if not from day to day, together with the state of the tumour. If not competent to make the examinations himself, the radiologist should seek the aid of a laryngologist or other clinician.

DOSAGE

The notation of dosage in distance mass therapy can be done by various methods. The total dosage could be indicated by milligramme or gramme hours; this, however, is most unsatisfactory unless all possible data are given—namely, quantity of radium, screenage, radium skin distance; frequency of treatments; duration of each treatment; total period of treatment; and number and position of ports of entry. Even then the dosage so indicated is the dosage given by the apparatus to any particular skin area. As the lesion-skin distance varies with the various ports and as the radium skin distance is also varied in some cases, the futility of such notation of dosages can be seen from Table I.

TABLE I.—*Dosage Data—2-gramme Bomb*

Based on measurements in water and assumption 1 imc. = 8·0 r/hr.

Ra-skin distance, cm.	Skin intensity in r/min.	Skin dose per hour in "r."	Percentage depth dose 10·0 cm. below skin.	Skin dose every hour in milli-grammes.
3·0	18·3	1100	5·8	2000
4·0	11·8	708	8·15	2000
5·0	8·3	498	10·1	2000
6·0	6·44	386	11·1	2000
7·0	4·75	285	13·2	2000

prepared by Mr. C. W. Wilson, assistant physicist to the Westminster Radium Annexe.

The only true method is to calculate or measure the dosage received by the tumour. For this purpose isodose curves have been prepared by the physicist of the department.* The intensity received by the tumour through various ports of entry can be obtained from the following curves prepared by Mr. Wilson (Fig. 5).

The total X ray dose on the tumour varies from one to two and a half erythema doses. This is made up by the fields already mentioned, and is approximately of the order of 1000 r. from the affected side, and 1300–1600 r. on the skin from the opposite side and the posterior field. No hard-and-fast rule as to the number of r. units to be given can be followed; every case must be judged as it proceeds and doses increased or treatment suspended according to the state of the tumour and the reactions. Numerous failures and increasing experience serve to strengthen our conviction that nothing short of the fullest possible dose on the tumour must be aimed at. This means that the skin will be damaged to a certain extent but this must be disregarded; if the treatment is given slowly enough, the skin will heal well and return to its original state. With larger quantities of radium and the possibility of still greater radium skin distances and harder X rays, it may be possible to deliver the necessary tumour doses without skin damage. In those cases where metastatic glands are present, the doses must necessarily be larger than where no palpable glands are noticed, as a larger volume of tissue has to be irradiated.

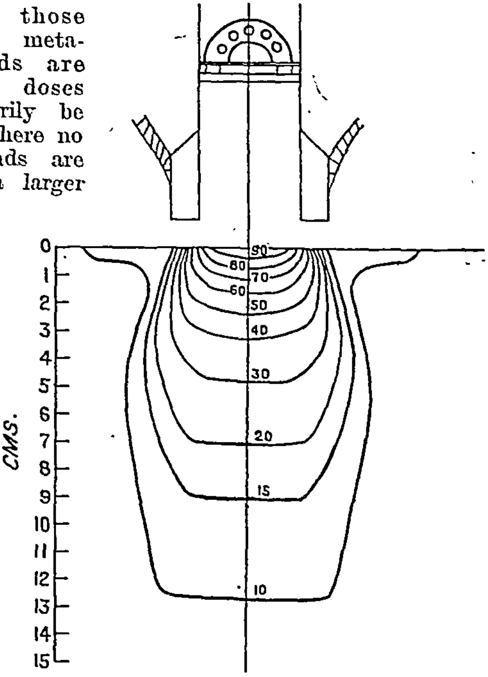

FIG. 5.—Isodose curves of the 2-gramme unit Westminster bomb. Radium-skin distance, 6 cm. Skin intensity, 8·0 r/min.

The total doses received by the tumour in the various successful cases is shown in Table II.

RESULTS

The number of cases treated by the combined method during the past three and a half years is shown in Table III.

The longest period of survival to date is three and a half years. One case died from other causes, free from disease by histological examination after complete post-mortem examination. Among the non-successful cases are two groups: (1) those, the majority, in which initial improvement and even total disappearance of the disease was followed by local recurrence within periods varying from 6 to 18 months; (2) those in which the disease progressed in spite of, and actually during the treatment.

CONCLUSIONS

(1) The combination of X rays and radium is a deliberate attempt to treat extrinsic laryngeal cancer by an irradiation of different wave-lengths, as this appears to increase the radiosensitivity of the tumour and to lead to retrogression of the disease.

(2) The treatment is safe and, as compared with the intensive methods of Coutard in Paris or Martin in New York, produces less cutaneous and mucosal destruction and is well tolerated.

(3) No claims are made either as to permanency of results or to a great percentage of clinical cures. Of a total of 52 cases of hypopharyngeal cancer, 17 remain free from disease for periods up to three and a half years.

(4) Two grammes of radium is not considered the best possible quantity, and the intention is to increase the bomb to four grammes in the future, and further as opportunity arises.

(5) Finally a few words as to the future—the possibilities of this method have not by any means been exhausted. Many mistakes have been made, and from these much has been learned. The question is, Will the method be an improvement on previous methods ? The brilliant results achieved with X rays alone by Finzi and Coutard are well known. On the other hand, equally wonderful results are shown to us by Berven with gamma rays alone. Is there, then, any special virtue in the two agents when used together which is not possessed by each when used alone ? We know that there is a biological difference in the effect produced by (say) infra-red and ultra-violet radiation. Why should there not also be such a difference, when using widely differing wave-lengths of X and gamma radiation ? Many tumours, when treated with one type of radiation only, will proceed to a state of partial regression and then remain stationary or start again in active growth. It is our contention that, with the combined method, the number of such partial successes is very materially reduced, and that when the process of regression begins to slow down under one wave-length, the addition of the other supplies the necessary stimulus to complete healing.

TREATMENT OF LOW-CALCIUM TETANY WITH CALCIFEROL

BY R. S. STACEY, B.Chir. Camb.

FIRST ASSISTANT IN THE MEDICAL UNIT, ST. THOMAS'S HOSPITAL, LONDON

LOW-CALCIUM tetany is met with in dietetic deficiency states, in disorders of the intestinal tract such as steatorrhœa, following thyroidectomy, and as an idiopathic condition probably due to hypoparathyroidism. It is with the treatment of the two latter that this paper is concerned.

Idiopathic tetany is rare, but owing to the frequency with which a subtotal thyroidectomy is now done, post-operative tetany is not uncommon. Many cases respond to calcium or acid medication, but others are met which cannot, by these means alone, be kept free from symptoms and some additional line of treatment must be sought.

As a treatment for an acute attack, parathormone, given intermuscularly is more convenient though less rapid in its action than the only alternative—namely, the intravenous injection of calcium salts—but its regular use over long periods has several disadvantages. It is expensive and, because of its relatively rapid action, difficult to control. Further, with prolonged use, there is some risk of decalcification and it has frequently been found to have a steadily decreasing effect.[1] [2]

As an alternative to parathormone various irradiation products of ergosterol have been given by mouth (for references see Reed and Seed,[3] Snapper,[4] Schultzer,[5] and Boothby).[6] Vitamin D, in the small doses used for the treatment of rickets, is usually ineffective in cases which do not respond to simpler methods of treatment. The following is a description of the course of three patients who have been treated for a considerable period on large doses of pure vitamin D (calciferol). In each case gelatin capsules containing 2 or 4 mg. calciferol (80,000–160,000 international units vitamin D) dissolved in olive oil have been used. A similar case was reported by Elliott [7] while the present paper was in preparation.

CASE RECORDS

CASE 1. *Post-operative tetany.*—On Jan. 5th, 1934, the patient, a woman of 24, underwent subtotal thyroidectomy for hyperthyroidism. The operation was quite straightforward and two small pieces of gland were left on either side of the trachea. The parathyroid glands were not seen. On the fourth day after operation a severe attack of tetany developed with laryngismus, carpopedal spasm, and a positive Chvostek sign; the serum calcium was 7·0 mg. per 100 c.cm. The attacks were controlled by parathormone, but recurred on discontinuing the injections. For the first nine days after operation there was an irregular pyrexia without any symptoms or signs to account for it. Fig. 1 shows the blood changes after the first six weeks after operation. The preliminary fall in the blood calcium is due to the discontinuance of parathormone treatment. From the first onset of symptoms the patient has had calcium gluconate grs. 180 t.d.s., and from the eighteenth week Thyroideum Siccum B.P. gr. ¼, t.d.s.

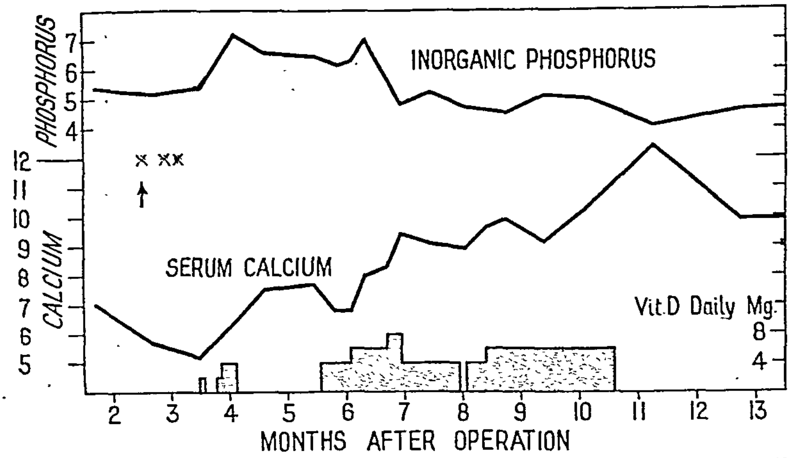

FIG. 1 (Case 1).—Changes in plasma inorganic phosphate and serum calcium with various doses of vitamin D. • = active tetany. ↑ = injection of parathormone.

CASE 2. *Post-operative tetany.*—The patient was 51 years of age and had a subtotal thyroidectomy done for toxic adenoma on Sept. 20th, 1934. Five days later active tetany developed and was controlled by parathormone injections and calcium gluconate grs. 180 t.d.s., for the following three weeks. Calcium gluconate has been administered ever since. On discontinuing the parathormone tetanic attacks occurred daily for a week when treatment with calciferol was started. The Table indicates the subsequent course throughout which tab. thyroid (sicc.) gr. ½ b.d., was given for a mild degree of myxœdema. After starting calciferol no cramps were experienced until Jan. 1st, 1935, when the serum calcium had fallen to 7·7 mg. per 100 c.cm. During the latter period, when the calcium ranged between 7 and 8 mg. it is interesting to note cramps were only experienced on the days immediately following the menstrual periods.

Mar. 14th ..	8·3	3·8	None.

b.d. = twice daily.

CASE 3. *Idiopathic tetany.*—Male, aged 33, a boot repairer. After an attack of influenza in January, 1933, the patient was seized with severe cramp in the hands. These continued intermittently, being brought on particularly, but not always, by work, till an exceptionally severe attack involving the muscles of the face and throat, making breathing difficult, brought him to hospital in March, 1933, in a typical tetanic attack. Blood calcium was then 6·2 mg. per 100 c.cm. He was treated with calcium chloride intravenously and parathormone and discharged free from symptoms with a blood calcium of 8·1 mg. As an out-patient he was treated on 2 pints of milk daily, calcium gluconate grs. 120 t.d.s., and Ostelin ♏ 3 t.d.s. (3000 units). Throughout the year he had invariably positive Trousseau and Chvostek signs with attacks of active tetany sometimes daily. At no time were there any other abnormal physical signs, nor any changes in skin, hair, nails, or lenses.

On Dec. 7th, 1933, when Fig. 2 starts, the calcium was 5·1, inorganic phosphate 8·0 mg. per 100 c.cm. A period of artificial sunlight resulted in a sudden rise in the calcium, a drop in the phosphate, and the disappearance of symptoms. A further period of artificial sunlight produced a similar effect on the phosphate but no corresponding rise in calcium. Shortly after starting calciferol both the Chvostek and Trousseau signs became negative. Fig. 2 shows the subsequent blood changes.

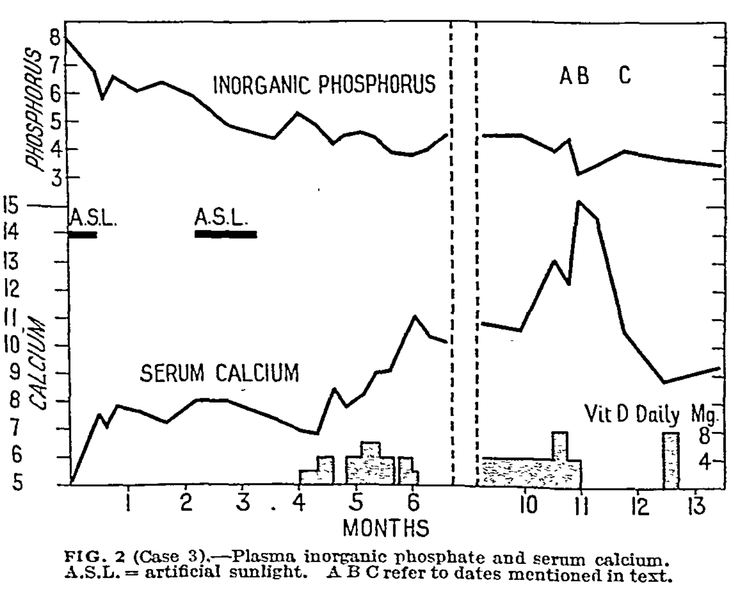

FIG. 2 (Case 3).—Plasma inorganic phosphate and serum calcium. A.S.L. = artificial sunlight. A B C refer to dates mentioned in text.

There has been one attack of active tetany only. This was not actually witnessed and all information concerning it rests on the patient's description. Three days later the serum calcium was 13·0 and the phosphate 3·5 mg. per 100 c.cm. Such attacks with a high calcium have been described by Reed and Seed.[3] The prolonged contraction of the small muscles of the hands which is required by the patient's work is a very sensitive test for latent tetany, and if the serum calcium is about 9 mg., cramps tend to develop after three or four hours' work when other signs of latent tetany are lacking. In his case, therefore, it is necessary to adjust the blood calcium with a greater nicety than would otherwise be needed.

ACTION OF CALCIFEROL

In all three cases the administration of calciferol in large doses has been followed by rapid relief of all symptoms. In Case 3 small doses of vitamin D, such as are used in the treatment of rickets, had been given without definite effect.

Concomitant with the relief of symptoms there was a rise in serum calcium. A distinct cumulative action is noticeable, the calcium continuing to rise without corresponding increase in dosage. On discontinuing the calciferol, the serum calcium does not at once return to its original level, but there is a delay of a month or more. For example, in Case 1, after the first period on calciferol, the serum calcium continued to rise for five weeks, and after the second it was well above the basal level ten weeks after the last capsule. Variations in the plasma inorganic phosphate follow a course roughly the converse of the calcium changes, tending towards a normal value. It will be noticed however that on starting on calciferol a sharp rise in the phosphate often occurs, followed later by a fall.

TOXIC SYMPTOMS

Reference to the literature for the toxic symptoms to be expected with calciferol is of little assistance because in most cases pure substances have not been used, and it is well known that the various irradiation products of ergosterol differ greatly in toxicity. Reed [8] states that large doses of viosterol produce: anorexia, nausea, vomiting, and diarrhœa; frequency of micturition without polyuria; loss of weight; muscular weakness, lassitude, dull aching in the muscles, muscular incoördination and disturbed equilibrium. In animals calcification of the heart, arteries, and kidneys has been produced and urinary calculi been found. Extreme overdosage results in decalcification of the bones.

In Case 1, after the patient had taken a total of 728 mg. calciferol during five months, she suddenly developed anorexia and occasional slight epigastric pains after meals. In six months her weight had fallen from 8 st. 4 lb. to 7 st. 11 lb. The hæmoglobin was 52 per cent. On discontinuing the treatment these symptoms at once disappeared; she started to gain weight and the hæmoglobin rose rapidly to 85 per cent. on iron. In Case 3 there was also a slight loss of appetite, but the patient's weight fell by only 3 lb. during four months in which he took 556 mg.

The urine has been examined regularly in all cases and there has been no albuminuria. The blood pressure also has remained normal and no abnormality of bone or kidney has been found radiologically.

In Case 3, with considerable calciferol overdosage and a serum calcium of 15 mg. per 100 c.cm., the serum developed a yellowish-brown coloration. The pigment was soluble in ether (unlike bile-pigments) and chloroform. No pigmentation of the skin or conjunctivæ could be detected. It was found that the depth of colour could be estimated satisfactorily by the icteric index, and the following Table indicates its subsequent disappearance. The letters refer to points in Fig. 2.

Date.		Icteric index.
Oct. 4th, 1934	A	23
,, 11th ,, ...	B	15
Nov. 1st ,, ...	C	10

In these cases then, provided there is no hypercalcæmia, some loss of weight and appetite, and in one case a considerable degree of anæmia, are the only toxic effects which have been observed.

METHOD OF TREATMENT

In treating a case with calciferol it is obviously necessary to supply adequate calcium in the diet for absorption and to minimise the risk of decalcification. To this end calcium gluconate and extra milk have been given.

The calciferol itself can be given either continuously or at intervals. The former requires, owing to the cumulative effect, frequent blood estimations. Recently the second method has been used with these cases and it has been found that a short period (e.g., seven days) on a fairly heavy dosage (4 mg. b.d.) is followed by a long period free from symptoms. A further short course is given when signs of latent tetany develop. The total amount of calciferol used is much less, if it is given in this way, and there has been no loss of weight or appetite. Periodic blood estimations are required to ensure against hypercalcæmia.

SUMMARY

(1) The progress of three cases of low calcium tetany, treated with calciferol, is described. (2) It has been found possible to maintain the patients free from symptoms with normal blood findings. (3) Possible toxic effects are discussed.

AZOTÆMIA IN ACUTE BRIGHT'S DISEASE

By J. BASIL RENNIE, M.D., F.R.F.P.S. Glasg,*
ASSISTANT PHYSICIAN TO THE ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW

(From the Department of Pædiatrics, Glasgow University, and the Biochemical Laboratory, Royal Hospital for Sick Children)

IT is not yet known how frequently the non-protein nitrogen (N.P.N.) of the blood is raised in acute nephritis, but there is evidence of an increase in a fair proportion of cases. MacLean [1] found that some accumulation of nitrogenous bodies in the blood takes place in all but the mildest cases, and Moorhead [2] stated that the blood-urea is almost always increased. Crawford [3] reports an increase of blood-urea in 70 per cent. of cases of acute nephritis in children, and Boyd,[4] also investigating children, found the N.P.N. of the blood to be very often above normal limits, while Lyttle and Rosenberg [5] observed azotæmia in 63 per cent. of 49 cases. Recently Murphy [6] and his collaborators recorded azotæmia in 71 per cent. of 94 patients, chiefly adults, suffering from acute nephritis.

Peters and Van Slyke [7] state that in acute nephritis the N.P.N. of the blood may be normal or very greatly increased; as a rule a moderate rise is found early in the disease. They have found that N.P.N. may be increased in the blood while a high concentration of nitrogen is present in the urine, and there may be actually a negative nitrogen balance. Hence they believe that azotæmia is not to be ascribed entirely to diminished renal function but is partly due to increased nitrogen metabolism resulting from the acute infection often present in acute nephritis.

---

* The work was done during the tenure of a Carnegie research scholarship.

The present paper records the N.P.N. of the blood of 98 children, estimated at various stages of the disease. All the patients were under thirteen years of age, and one could be reasonably sure that they were all suffering from acute Bright's disease uncomplicated by chronic cardiac or renal lesions. The method used was that of Folin and Wu.

THE FINDINGS

Incidence.—The number of children admitted to hospital in the first week of the disease was 63, of whom 38 (60 per cent.) showed a N.P.N. over 40 mg. per 100 c.cm. (the upper limit of the normal), 7 having a concentration of over 100 mg. Of the 35 patients admitted in the second week of illness, 18 (51 per cent.) showed azotæmia, 3 having a blood N.P.N. of above 100 mg.

Relation to the Blood Pressure.—No relationship could be found between the level of N.P.N. and of the blood pressure; high readings were obtained with the sphygmomanometer when there was no azotæmia, and, on the other hand, a considerable rise of N.P.N. was not uncommon when there was no rise in blood pressure.

Relation to Œdema.—The amount of œdema gave no indication of the degree of azotæmia. Some cases with massive œdema showed no rise in N.P.N., while others, equally œdematous, had definite azotæmia. From Table I. it will be seen that the average value for blood N.P.N. in cases without œdema was no greater than in those with obvious dropsy.

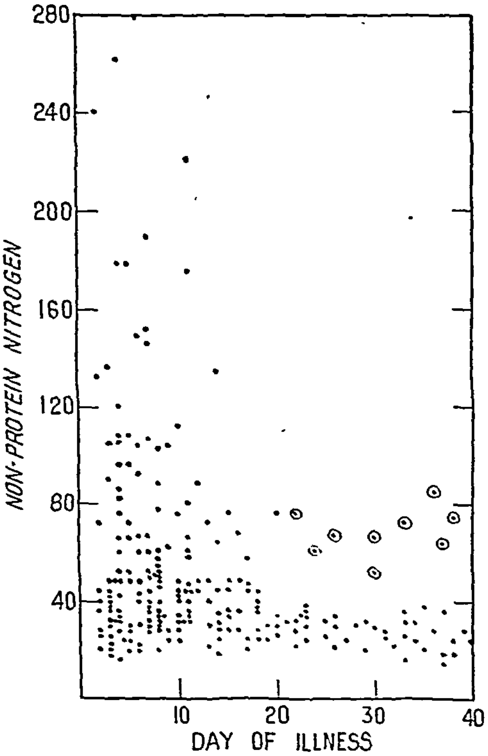

FIG. 2.—Azotæmia in acute Bright's disease (220 observations on 98 cases). ⊙ =persistence of azotæmia after third week, indicating grave prognosis.

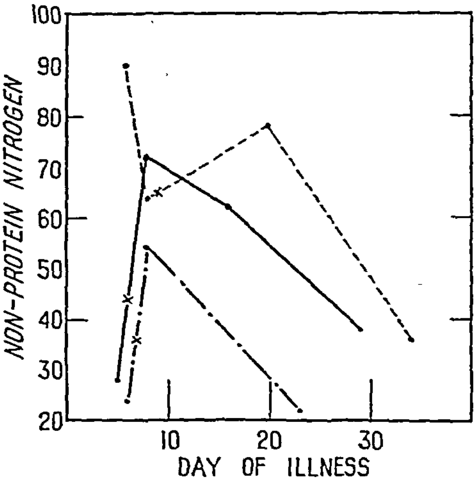

FIG. 1.—Rise in non-protein nitrogen (mg. per 100 c.cm.) after cessation of cerebral manifestation in acute nephritis. × =convulsions ceased following withdrawal of blood and cerebro-spinal fluid.

Cerebral Manifestations.—It is known that the N.P.N. is by no means constantly above normal in acute nephritis with nervous manifestations; nor is there any relation between the incidence or severity of the convulsions and the degree of azotæmia (MacLean,[1] Boyd,[4] Aldrich,[8] Nobécourt,[9] Holt[10]). Indeed Evans[11] has lately reported 7 cases in only 1 of which the N.P.N. was raised and that but slightly. Of the cases under my observation 12 showed cerebral manifestations, and 8 of these had azotæmia, the highest N.P.N. being 280 mg. per 100 c.cm. Two of these patients died. The level of the N.P.N. proved to be of no prognostic value: the patient with the highest level did not die although after eighteen months there is still evidence of kidney damage.

TABLE I

Œdema and Non-Protein Nitrogen

Œdema.	Cases.	N.P.N. mg. per 100 c.cm.	
		Average.	Range.
0	12	60·0	20·6–190·0
− +	29	49·6	19·1–113·0
+	27	55·4	22·4–176·5
+ +	30	63·5	17·0–280·0

One patient, semi-conscious on admission, with a N.P.N. of 280 mg., did not develop convulsions until four days later when that level had fallen to 133 mg. In 3 cases the N.P.N. actually showed an appreciable increase after the cessation of all nervous manifestations (Fig. 1).

VALUE OF N.P.N. ESTIMATION IN PROGNOSIS

Fig. 2 shows the results of 220 observations on 98 cases of acute nephritis. In all but 4 cases the azotæmia, when present, had disappeared by the fourth week of the disease. The observations made on these cases after the third week of the disease are indicated in Fig. 2 by ringed dots. Two of these patients died and gross renal damage persisted in the other two. The 5 other deaths in the series occurred from some complication such as pneumonia or meningitis.

In the large majority of cases a fall in N.P.N. coincided with loss of œdema, fall in blood pressure, and diminution of hæmaturia and albuminuria. There was no recognisable relation between the height of the N.P.N. at the commencement of the illness and the ultimate result. High levels were generally associated with satisfactory convalescence later, whereas 4 cases approaching the nephrotic type, with normal N.P.N., ran the usual chronic course. These results confirm the general opinion that little information can be gained from a single observation of the N.P.N. in acute nephritis. It appears, however, that repeated analysis is a guide to prognosis, since in the present series death or permanent renal damage occurred in all the cases where the N.P.N. remained above normal after the third week of illness.

TABLE II

Fall in N.P.N. of Blood with Comparatively High Protein Intake

RELATION OF DIET TO AZOTÆMIA

It has long been customary, because of the acute inflammation of the kidney and consequent diminution of renal excretory power, to impose on the patient with acute nephritis a very restricted diet, at least in the early stages of the disease. Protein in particular is held to be harmful, apparently because of the azotæmia. Ellis,[12] Fishberg,[13] and others have emphasised this point and recommend virtual fasting in the first days of the illness, only fruit juice and a quantity of water being permitted. More recently Bennett[14] has suggested that the fall in blood-urea in acute nephritis is attributable to this meagreness of diet, citing a case where a blood-urea of over 200 mg. per 100 c.cm. returned to normal in about ten days. While this is an attractive hypothesis, it should be mentioned that there are few figures available relating to behaviour of the N.P.N. in pati taking more food.

In the cases here recorded the routine diet admission to hospital was milk or milk and w varying in quantity with the age of the pati The amount of protein ingested ranged from 1 51 g. daily. In Table II. are shown 7 cases (Nos. in which azotæmia was present on admission an which the N.P.N. returned to normal within t weeks. Even from this small number it seems j fiable to conclude that fasting is not essential a rapid fall in the N.P.N. level, and that a consi able amount of protein in the diet does not inter with the fall. Table II. also includes 2 c (Nos. 8 and 9) in which the N.P.N. of the blood not rise, although the patients were having each over 3 g. of protein per kg. of body-weight.

These observations show that a diet of milk, taining a considerable amount of protein, has apparent adverse influence on the azotæmia of a nephritis. There seems to be no necessity for "fasting diet," since the N.P.N. falls spontaneou as the condition improves (Fig. 2).

It may be objected that the ingestion of s quantities of protein in the early stage incre the likelihood of residual damage to the kidney. meet this objection I shall briefly describe the su quent fate of the cases discussed in this paper, period of observation extending from January, 1 to the present date. There have been 7 deaths which 2 were apparently a direct result of the nephr and 5 were due to pneumonia or meningitis. patients were transferred to isolation hospitals taken home by their parents; about these no fa are available. The remaining 85 attend hosp as out-patients and 55 show no evidence of re disease. The other 30 have albuminuria of vary degree, 2 of them with moderate azotæmia a elevation of blood pressure. Some of these have been long under observation, but earlier experie suggests that a substantial proportion will make complete recovery. This recovery-rate compa well with others on record.[4,5,6,15] and indicates t a diet containing an adequate quantity of protein not an adverse influence.

SUMMARY

(1) Among 98 children suffering from acute nephri azotæmia was found in 60 per cent. of those fi examined within seven days of the onset, and 51 per cent. of those first examined in the second wee (2) The degree of azotæmia bore no relation eith to the amount of œdema or to the height of t blood pressure. (3) The non-protein nitrogen of t blood bore no relation to the incidence or the severi of the cerebral manifestations in acute nephrit (4) A single observation of the non-protein nitrog of the blood early in the disease is of no prognost value. In this series persistence of azotæmia aft the third week of illness is found to be of gra significance. (5) A sufficiency of protein in the di does not militate against disappearance of azotæm and has apparently no harmful effect.

I am indebted to Prof. G. B. Fleming, Dr. Stank Graham, and Dr. Noah Morris for their help.

AMOUNT OF HÆMOGLOBIN IN THE BLOOD

By Ensor Roslyn Holiday, B.M. Oxon.

FREEDOM RESEARCH FELLOW, LONDON HOSPITAL
(From the Hale Clinical Laboratory and the Medical Unit, the London Hospital)

In spite of the many investigations which have been made on blood the following statements can scarcely be disputed:—

1. The amount of hæmoglobin in a given volume of blood cannot be accurately estimated.
2. The percentage of hæmoglobin relative to a "normal" standard is accurate only for the apparatus employed, and differs widely with different instruments.

This paper attempts to survey critically the hæmoglobinometers in present use, and the methods by which they are standardised. A method of determining the relative amounts of hæmoglobin in different bloods, and suitable for routine use, is also described. It depends upon a physical property of oxyhæmoglobin the measure of which is permanent, capable of exact assessment, and of being used as a reference standard for other forms of hæmoglobinometer.

METHODS OF ESTIMATING HÆMOGLOBIN

For clinical purposes it has been customary to compare the colours of solutions of hæmoglobin or its derivatives in order to estimate the hæmoglobin concentrations. Less commonly the light transmitted by a solution has been measured electrically. The other methods available, namely, to find the oxygen-combining capacity, or the iron content, or the extinction coefficient at the head of the α or β bands, are too complicated for routine use, but have been employed in standardising the colorimetric or photo-electric hæmoglobinometers, and for research purposes. They will be discussed here only in relation to standardisation of hæmoglobinometers, though they are really more fundamental methods of estimating hæmoglobin.

1. *Colorimetric hæmoglobinometers.*—The large number of papers which are still appearing describing new hæmoglobinometers is an indication of the unsatisfactory position of the technique. The colorimetric methods have various degrees of refinement. They have the great practical advantage that a simple portable apparatus only is necessary. They enable a single observer who is optically sensitive to colour shades to compare one blood with another, with an accuracy which may be sufficient for clinical purposes. Unfortunately, everyone is not sensitive to slight colour differences, and moreover different results may be obtained with the same instrument by two observers each believing himself to be colour-sensitive. This makes colorimetric methods objectionable for routine work in a large hospital where there are several observers. That significant errors are thus introduced is shown in Fig. 1, where readings taken with the Dare colorimetric method, formerly in routine use in the Hale clinical laboratory, are compared with a method to be described later. Colorimetric readings have the further disadvantage that, while differences in colour shade are easy to read in the lower parts of the scale, they are obscure in the higher parts, where a slight difference of shade represents an appreciable range of hæmoglobin concentration. They are also difficult to make in artificial light and in the presence of bilirubin. It is difficult, if not impossible, to compare colorimetric results from different laboratories for the above reasons, and also because there are also wide differences between the "normal" standard of instruments of various types.

2. *Physical instruments.*—Spectrographic methods were used for estimation of hæmoglobin concentrations at the end of the last century, although the instruments were crude, compared with the modern spectrophotometer. In recent years, photo-electric methods of measuring the light transmission through hæmoglobin solutions have been elaborated, as for example by Davis, Sheard, Sanford, and Osterberg.[1-5] These instruments have a great advantage over the colorimetric ones in that there is no personal factor, but they are usually more bulky and more expensive. There is no question as to their superiority for both routine and research work. The photo-electric hæmoglobinometer in routine use in the Hale laboratory is described in detail at the end of the paper. It differs from that of Sheard and Sanford in that use is made of the intense Soret absorption band on the border of the ultra-violet instead of the better known α and β bands.

STANDARDISATION OF HÆMOGLOBINOMETERS

(*a*) *General.*—Whichever hæmoglobinometer is used, a figure is obtained which is some function of the amount of hæmoglobin in the blood examined, and each type of instrument has to be standardised.

Ideally a hæmoglobinometer should be standardised on hæmoglobin solutions, made from known weights of pure dry human hæmoglobin crystals. Hæmoglobin crystals are difficult to prepare from any blood, and have only recently been reported as made from human blood.[6] Pure dilute hæmoglobin solutions can be made from blood, especially if low temperature rooms are available, but they are unstable. The ideal method of standardisation is therefore a counsel of perfection, at present impracticable.

(*b*) *Chemical methods of standardisation.*—The chemical methods which are available are two: to determine the iron content, or to find the oxygen-combining capacity. It may be taken that a solution of hæmoglobin, completely saturated with oxygen, contains as many atoms of iron as it does molecules of oxygen, although it is not known how the oxygen is attached.[7]

There appear to be two forms of hæmoglobin in normal human blood,[8] and it is an assumption that the relation between colour and oxygen-capacity of

both are identical. The number of iron atoms per molecule of hæmoglobin is probably four; it was formerly thought to be one. The iron estimation has not been in common use for the estimation of hæmoglobin in blood, partly because there is iron in blood in other forms, although in small amounts. It has not often been used for pure hæmoglobin solutions as the analysis was until recently thought to be technically more difficult and less accurate than the oxygen capacity. But recently Alt [8] has compared the estimation of hæmoglobin from blood iron analyses with the Sahli, Newcomer, and Dare colorimetric methods; Brown and Briggs [9] have compared the estimation of hæmoglobin by iron and by oxygen analyses; Haden [10] and Dowden and McNeill [11] have also shown that iron estimations in blood are reliable, and advocate strongly their use for hæmoglobinometry. The above authors all use either the modified Wong [12] method, or Kennedy's [13] method. Either can be completed in 15 minutes, and the latter method does not require continuous attention during that time.

The oxygen-capacity can be measured by the Barcroft, Haldane, or Van Slyke methods. All these depend on the interaction between oxyhæmoglobin and potassium ferricyanide, for which no chemical equation can be written. It has been shown that the oxygen is liberated *almost* quantitatively. But in blood the potassium ferricyanide reacts to a slight extent with other substances besides oxyhæmoglobin, and also if the freed oxygen is left in contact with the reactants some of it is reabsorbed.[15-20] In the Barcroft and Haldane methods the oxygen is liberated into an air space at atmospheric pressure, and several minutes are allowed for equalisation of temperature before a reading of volume is taken. In the Van Slyke apparatus the reactants are very vigorously shaken for three minutes, and the gas is liberated into a vacuum. Its volume at constant pressure, or its pressure at constant volume, is then read as soon as the experience of the observer allows. Each of these methods gives reproducible results in the hands of an expert. The Van Slyke method tends to give the highest readings, and the Barcroft the lowest. It has been questioned whether the differences between the Van Slyke and Haldane methods are statistically significant.[21] It seems impossible to say which figure represents the true oxygen-combining capacity of the hæmoglobin in the blood. An added difficulty occurs when purified hæmoglobin solutions are used, as these very readily form methæmoglobin from part of the oxyhæmoglobin, and in this molecular rearrangement the oxygen is not freed by potassium ferricyanide. This introduces an error which is common to all three methods.

(*c*) *Physical method of standardisation.*—Hæmoglobin solutions may be compared by their extinction coefficients. The light, of a given wave-length, absorbed by a solution is related to the concentration and the thickness of the absorbing layer. By means of a spectrophotometer one can measure the relative intensities of the incident light (I) and the transmitted light (I′) for a given solution.

This ratio is related to the concentration (c) and the thickness (d) by the equation

$$\log_{10}\frac{I}{I'} = Ecd$$

where E, the extinction coefficient, is a constant for the substance in solution. This is known as Beer's law. It implies that log I/I′ is proportional to the product of the concentration and thickness of the solution, and that if the thickness be kept constant then the extinction coefficient will be proportional to the concentration. Provided that Beer's law is obeyed the extinction coefficient is a reliable constant. Newcomer [22] and Butterfield [23] have shown that the law holds for oxyhæmoglobin solutions for dilutions from 1 : 1 to 1 : 2000. We have confirmed the law over the range 1 : 100 to 1 : 5000.

Modern methods of measuring extinction coefficient are accurate to within ±2 per cent.[24] and results obtained with various instruments of different make and design agree very well with one another. From these considerations the extinction coefficient seems, at present, to be a reliable and universally reproducible standard for the standardisation of hæmoglobinometers.

METHODS OF EXPRESSING RESULTS

The amount of hæmoglobin estimated may be expressed either as the number of grammes in 100 c.cm. of blood, or as a percentage of the amount present in a "normal" individual. Both courses present difficulties.

A. *Hb. as grammes per cent.*—It is admittedly desirable, as some American workers [25-28] have recently emphasised, that the results should be expressed in terms of grammes of hæmoglobin per 100 c.cm. This, however, is not yet possible. To attempt to do so would, in our opinion, imply a false degree of accuracy. Peters and Van Slyke [29] are also of this opinion. They state: "The maximum volume of oxygen combining with 1 g. of hæmoglobin is a value concerning which we have, for human hæmoglobin, no reliable data."

In expressing hæmoglobin concentration in grammes per cent. it has been customary to use the figures given by Hüfner [30] in 1894. He stated that 1 g. [illegible] oxyhæmoglobin combines with 1·338 c.cm. of [illegible] at normal temperature and pressure, and [illegible] 0·336 per cent. Fe. With these factors [illegible] of hæmoglobinometers by chemical [illegible] has been translated into grammes of hæmoglobin per 100 c.cm. This has involved two assumptions. First, that Hüfner's figures are correct, [illegible] that the values are the same for ox and [illegible] hæmoglobins. Hüfner's paper is in a journal which is perhaps not easily accessible, and cannot have been widely read. His figures were obtained in the following way.

[illegible] assumed that the oxygen capacity was equal to [illegible] CO capacity. He separated corpuscles from plasma, diluted them with 0·1 per cent. NaOH to four times the volume of the blood from which they were obtained. [illegible] reduced the oxyhæmoglobin completely by letting it [illegible] overnight with hydrazine hydrate. The N_2 which [illegible] evolved in the reaction was removed by suction with a filter pump. The flask of reduced hæmoglobin was then attached to a vessel containing pure CO [illegible] manometer, and the change of gas volume due to [illegible] CO was measured. The amount of hæmoglobin in the solution was then estimated spectrophotometrically (in 1894!) by finding the extinction coefficient of a solution made from dry hæmoglobin crystals prepared from ox blood. Eight solutions were analysed in this way, 6–10 readings being taken of each. A correction had to be applied for dissolved CO. An attempt was made to do analogous experiments on solutions of hæmoglobin crystals, but very discordant results were obtained. This Hüfner attributed to the difficulty of getting the crystals alcohol-free, but it may have been due to the instability of pure hæmoglobin solutions, which has been found by later workers and has prevented them from repeating his work.

It is obvious that Hüfner's method of determining the oxygen-capacity cannot be compared with current methods. The figure he obtained, however, was confirmed by that calculated from iron analyses on ox hæmoglobin crystals, one preparation being analysed by himself and another by Jaquet in Basle. The crystals were dried to constant weight, ashed in a muffle oven, redried and titrated with potassium permanganate. Haldane [31] did not place any reliance on Hüfner's figures. He pointed out that the results of individual experiments differed by 10 per cent.; he thought the method theoretically objectionable, and the arbitrary correction which was applied for dissolved CO of questionable accuracy and of important magnitude. Later, Hüfner tried the ferricyanide method, and found results at least 13 per cent. lower than he had obtained by his previous method.

It will be seen that the "Hüfner factor" of 1·34 cannot be considered a satisfactory standard on which to base calculations for the conversion of oxygen-capacity determinations by Van Slyke, Haldane, or Barcroft methods into grammes of hæmoglobin per 100 c.cm.

B. *Hb. as per cent. normal.*—The "normal" hæmoglobin has been reported by many observers, using various hæmoglobinometers, variously standardised. Some of the data have been summarised into a diagram by Peters and Van Slyke.[32] The large variation among normals is probably not due merely to differences in method and observer. There is also a change with age and difference with sex. There has been much discussion on the supposed differences between English and American bloods in regard to hæmoglobin concentration. The 100 per cent. of the Haldane hæmoglobinometer is based on the estimations of Haldane and Smith,[33 34] which show that the mean percentage oxygen-capacity of 14 "normal" English individuals was 18·5 c.cm. per 100 c.cm. blood. The figures obtained varied between 16·0 and 20·9 c.cm. and sex or ages are not stated. They were obtained by making the subjects breathe a known volume of pure CO, and then estimating colorimetrically the percentage of CO in their blood. Hence the amount of blood could be calculated, and also the amount of CO, or oxygen, which would be necessary to saturate it completely, and the oxygen capacity per 100 c.cm. Here again the method used to find this "standard" figure is not one which is in modern use. Haldane [34] confirmed the figure later on 12 males, between 16 and 62 years of age, using the ferricyanide method.

Using the Haldane hæmoglobinometer Price-Jones [21] has found the mean of 100 male students in London to be 105 per cent., and that of 20 male students in Boston, U.S.A., using the same instrument, 112 per cent. The only difference in his experiments in the two places seems to have been that in England capillary blood was used from an ear-prick, while in America venous blood was used as more than one analysis was made on each sample. Oxygen-capacities were determined on the samples used by Price-Jones in America by the Van Slyke method in Dr. Dill's laboratory, and by the Haldane method by G. P. Wright. It will be noticed that the number of American students examined was small.

Price-Jones and Vaughan [35] have recently determined the hæmoglobin value of venous and capillary blood in 90 normal English males, using Haldane's colorimeter method. There was no significant difference between the hæmoglobin values for venous and capillary blood. The mean value for venous hæmoglobin was 105·46 per cent.; the possible limits of normal calculated as + and − three times the standard deviation were 120·44 per cent. to 90·48 per cent. These estimations were made by Vaughan using her own apparatus, including pipettes calibrated by one of us (P. M. T. K.), and the figures are in striking accord with the earlier series of Price-Jones in London. In order to establish the accuracy of the method as employed by Vaughan ten consecutive estimations were made on the same sample of blood. The mean obtained was 102·4 per cent. ± 0·18 per cent. The standard deviation was 0·8 per cent. ± 0·12 per cent. and the variability was 0·78 per cent. ± 0·12 per cent. In America the "normal" is usually taken to be 20·9 vols.[36] oxygen per 100 vols. or 15·6 g. Hb. per 100 c.cm. using Hüfner's figure, and this corresponds to about 114 per cent. on Haldane's scale. Sokhey,[37] using the Van Slyke oxygen method, found that the mean of 121 Indian males in Bombay was 111·3 per cent. Haldane. Jenkins,[38] in Salford, found a normal of 115 per cent. Haldane in a study of 53 males with a flicker hæmoglobinometer. Jenkins and Don,[39] using a Van Slyke constant pressure apparatus for oxygen determinations, tested bloods sent from London, Cambridge, Liverpool, Sheffield, Salford, and Altrincham, and found the mean to be 115 per cent. Haldane for 118 males, and 100 per cent. for 116 females. The figures ranged from 100–138 per cent. for males and 75–123 per cent. for females. It may be objected to this work that the samples were sent from far to be tested, and that the delay may have caused changes. Whitby and Hynes [40] found the mean Hb. of 50 normal London males to be 112 per cent., standard deviation 7·3 per cent., variability 6·5 per cent., limits 100–126 per cent., using the Haldane method. It seems unwise to conclude that there is a fundamental difference between English and American bloods while the techniques are still so difficult and the normal is so variable.

DISCUSSION

From the foregoing considerations it is clear that there is a great need for some basis of standardisation of hæmoglobinometers which would render hæmoglobin values wherever and however measured capable of direct comparison.

Obviously the most satisfactory means of standardisation would be afforded by known concentrations of pure hæmoglobin. As this is not yet practicable, recourse has to be made to certain chemical and physical constants of hæmoglobin. Iron content and "extinction coefficient" at the head of one of the absorption bands of hæmoglobin are the most reliable and easily determined constants of hæmoglobin.

At the time we standardised our hæmoglobinometer the methods for determining iron were laborious and of doubtful accuracy, as mentioned above, and, having means for measuring the "extinction coefficient," we calibrated the hæmoglobinometer here described, using this constant as a basis. If, therefore, at any time pure solutions of hæmoglobin become available it will be possible to relate the "extinction coefficient" measured on such a solution directly to the concentration of hæmoglobin, and by that means refer the hæmoglobinometer readings to concentrations of hæmoglobin.

The question of normality is of secondary and local importance. As Haden suggests, it should be determined for each particular laboratory or locality. In our case we have taken the mean of 70 values obtained from members of the London Hospital staff and students as the "normal." Fifty of these cases were also very kindly measured by Dr. Janet Vaughan, using the Haldane method. From these cases we find that our normal corresponds with 105·5 per cent. on the Haldane scale with a standard deviation of 2·84 per cent. (Fig. 1).

The normal value has been translated into terms of extinction coefficient by parallel determinations with the photo-electric hæmoglobinometer and a Hilger quartz spectrograph with "Spekka" photometer on the blood of forty-two subjects whose blood varied in hæmoglobin concentration from 20 to 120 per cent. of the normal value. The details are given below.

We find that our "normal" corresponds with an extinction coefficient at λ 412·5 mμ of $1{\cdot}20 \times 10^3$ for a thickness of layer of 1 cm., from which can be calculated the fact that the Haldane normal corresponds to an extinction coefficient of $1{\cdot}14 \times 10^3$.

DETAILS OF PHOTO-ELECTRIC APPARATUS

The apparatus was designed for routine use in the London Hospital where 40–50 hæmoglobin estimations are made each day. It was therefore primarily required to be simple to work, rapid and accurate in the hands of the unskilled observer, and to be free from any variations which might require it to be continually tested or recalibrated. The question of portability did not arise as all determinations could quite easily be made in the laboratory where the instrument is permanently housed in a cupboard. The electrical circuit, which is standard practice, was chosen for its accuracy and simplicity. A 0·5 megohm resistance (R_1) is connected in series with a potassium vacuum photo-electric cell and with a 36 volt battery which supplied the accelerating potential. The potential difference across R_1 is proportional to the photo-electric current. This potential difference is measured by means of a slide-wire potentiometer and sensitive galvanometer connected as shown in the diagram (Fig. 2).

Of the three characteristic absorption bands of hæmoglobin *the "Soret" band at λ 412·5 mμ was chosen for* measurement for the following reasons: (*a*) The absorption of the Soret band is seven times more intense than that of either the *a* or *β* visible bands. This allows of measurement on volumes of blood which can be obtained from pin-prick samples 5 to 10 c.mm. (*b*) The Soret band is well separated from any other band. (*c*) Owing to its greater intensity errors introduced by pigments other than hæmoglobin—e.g., bile-pigments—are insignificant (<1 per cent.).

This region of the spectrum was isolated by two superimposed Wratten filters (Nos. 35D and 47). The light source is a 36 watt 12 volt car lamp which is run off accumulators. These are charged at a rate which is ⅛ ampere less than that taken by the lamp. In this way a steady light can be maintained (variation 0·5 per cent.) for an hour or two and all sudden fluctuations of the mains are eliminated. A circular flask, filled with water, absorbs heat rays and causes a roughly parallel beam of light to fall on the cathode of the photo-electric cell. It is usual in such an arrangement to hold the solution to be measured in a container, with parallel sides, the light traversing the cell horizontally. The cell may be open, the solution being pipetted in from above, or completely closed, the cell being filled and then one of the transparent faces applied and clamped. Both these methods require that the two faces of the cell should be parallel and that the dilution of the blood should be accurate. This necessitates (1) an expensive cell, (2) accurate measurement of blood volume, (3) accurate measurement of volume of diluting fluid. We have avoided (1) and (3) by reflecting the light beam so that it passes vertically upwards through the containing cell. This allows of having a cell with only one transparent face (at the bottom). In such an arrangement what will determine the amount of light absorbed is the total quantity of hæmoglobin in the container; *if the light beam were truly parallel the* absorption should theoretically remain constant whatever the dilution, provided that the amount of hæmoglobin in the cell remains constant and the light beam occupies the whole cross-section of the cell. We have attempted to fulfil these conditions in the apparatus. The containing cells, of which we have 20, are accurately *bored to the* same diameter and are made from some inert material. Discs are cut from first quality plate-glass and can be fixed at the lower end by means of a screwed ring. It is essential that all the hæmoglobin present should be fully oxygenated. We have assumed that with the dilutions we use (1 : 500) there is sufficient dissolved oxygen in the diluting fluid to ensure the saturation of the hæmoglobin in 10 c.mm. of blood.

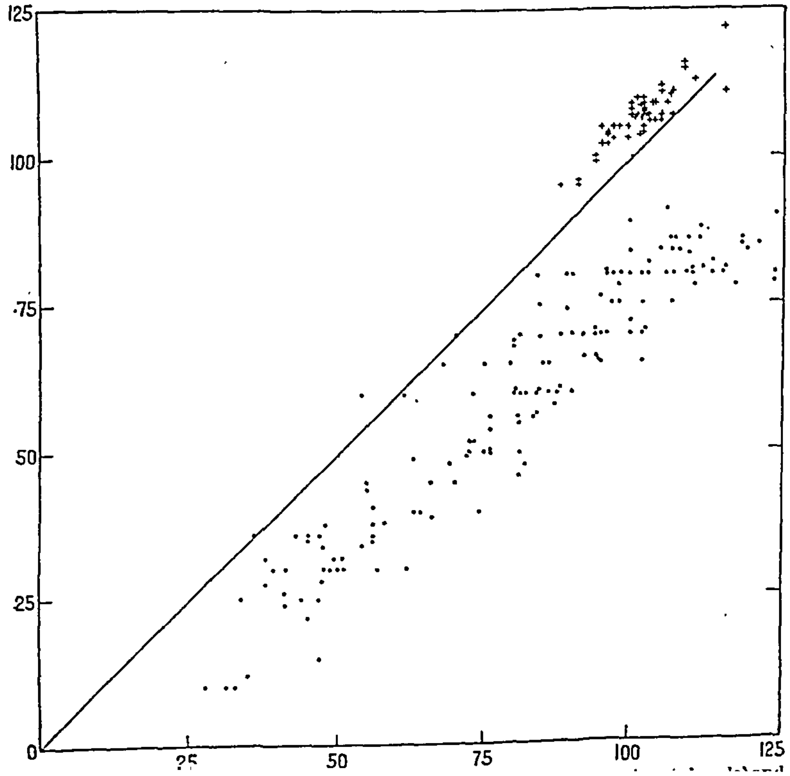

FIG. 1

the three instruments ga

PROCEDURE

The cells after cleaning are assembled, and into each are pipetted 5 c.cm. of 0·1 per cent. *sodium chloride* solution. This need only be a rough measurement. We have found that this diluting fluid gives us the most stable solutions of hæmoglobin, the usual alkaline fluids causing continuous and gradual conversion of the hæmoglobin to alkaline hæmatin. The strength we have chosen is such that the blood is completely hæmolysed and yet prevents precipitation of euglobulin. Each cell is covered with a lid. They are taken in batches of 10 to 15 into the wards. From an ear-prick 10 c.mm. of blood pipetted into one of the cells and the solution stirred once or twice with the pipette. The hæmoglobin should be determined within the next three hours. The light source and charging current are switched on about 10 minutes before measurements are to be made. After this time has elapsed the instrument is *standardised* as follows.

A slide is provided which holds a cell containing the hæmoglobin solution, and also an aperture closed with a piece of signal green glass, of known light-absorbing power. The slide is moved so that the glass is in the light beam. The potentiometer pointer is brought to the mark "standard." The galvanometer is brought to zero reading by a coarse resistance R_2 (Fig. 2) and a fine resistance R_3. The slide is now moved bringing the hæmoglobin into the light beam, then the galvanometer is brought to zero by adjusting the potentiometer. The reading of the potentiometer when read off against a calibration curve gives the hæmoglobin percentage of the blood. The procedure takes about 10 seconds. We usually make two or three readings.

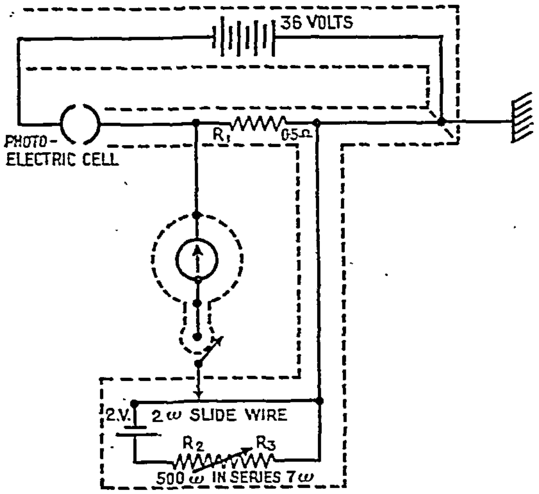

FIG. 2.—Plan of circuit.

CALIBRATION

The instrument is calibrated against values of extinction coefficient (measured on a Hilger quartz spectrograph (medium) with a spectrophotometer) for a series of 42 bloods. For each blood 4 dilutions were made and these measured both on the spectrograph and on the hæmoglobinometer.

In this way a curve was drawn through about 150 points relating hæmoglobinometer reading to "extinction coefficient." The standard deviation of points from the mean curve was found to be 0·25 scale divisions of the potentiometer for the whole curve. It is less for the weaker bloods and increases slightly for more concentrated bloods. In terms of hæmoglobin value it corresponds to a standard deviation of 0·1 per cent. for a 20 per cent. normal blood, 0·7 per cent. for a normal blood, and 2·0 per cent. for a 150 per cent. normal blood.

OLD "LABORATORY" STRAINS OF THE POLYMORPHIC TRYPANOSOMES

BY H. LYNDHURST DUKE, O.B.E., M.D., Sc.D. Camb.

DIRECTOR OF THE HUMAN TRYPANOSOMIASIS INSTITUTE, ENTEBBE, UGANDA PROTECTORATE

IN a recent paper on the chemotherapeutic susceptibility of trypanosomes, Browning and Gulbransen[1] describe a strain of *Trypanosoma brucei*, maintained in mice, as being at first "imperfectly accommodated" to this species of vertebrate host. During the early phases of its career in these little animals the trypanosome was found to be relatively resistant to various trypanocidal drugs. Later on, the strain became "highly accommodated and its pathogenicity increased to a maximum" and then the infected mice were readily cured with these same drugs. This description has suggested a few reflections from a different biological viewpoint, from one whose experience of these trypanosomes has been derived from strains freshly isolated from their natural environment in the tsetse areas of Central Africa.

Among the changes that may occur in trypanosomes during prolonged maintenance by direct passage in laboratory rodents two are of special importance. One is loss of the power to develop in tsetse, and the other is increase in virulence. A third character which may also change is pathogenicity to man.

TRANSMISSIBILITY TO THE TSETSE

The first phenomenon can only be demonstrated when clean tsetse are available in adequate numbers, and has been hitherto almost entirely overlooked in the routine evaluation of the characters of strains kept up in European laboratories. If, however, as indeed appears certain, *T. gambiense*, *T. rhodesiense*, and *T. brucei*, are essentially dependent on tsetse for their survival in nature, surely one of the most important of their many characters is the power to develop cyclically in the fly? Once a strain has lost this quality it retains for the student of human trypanosomiasis an interest mainly academic. There is good reason to believe that many old laboratory strains are actually unable to develop in glossina.

It is remarkable how completely this property of transmissibility has been ignored by most investigators of the polymorphic trypanosomes. At Hamburg, Reichenow and his colleagues have studied what appears to be a closely associated if not identical character, the culturability of these organisms in artificial media. Otherwise no one has yet attempted seriously to examine the accuracy of the conclusions reached on this subject in Uganda during the last ten years.

It seems to me probable from a careful study of Taylor's admirable work in Nigeria [2] that there were actually one or two non-transmissible strains among those under his purview. His main objective, however, led him in other directions and the opportunity has not recurred. In his introductory remarks Taylor thus refers to my views: "If this total loss of transmissibility occurs in nature with any frequency, and Duke's analysis of East African *T. gambiense* strains suggests this, then it would seem that *T. gambiense* strains are constantly becoming extinct, a conclusion of very considerable importance from the epidemiological standpoint."

My own experience of naturally occurring non-transmissible strains has been derived entirely from *T. gambiense* regions in Uganda and the Belgian Congo where *Glossina palpalis* is the only tsetse. Even here they were exceptional, and to demonstrate satisfactorily this peculiarity in the laboratory demands of course the dissection of large numbers of tsetse. I have met with only one non-transmissible "wild" strain of *T. brucei*, and none of *T. rhodesiense* in its typical form virulent to man.

VIRULENCE

The second modification, increasing virulence, may occur in nature. It is possible that direct transmission by glossina plays an accessory part in the spread of the *brucei* group in nature, in the form of epidemics in man or domestic animals. But an event of this kind is incidental to the normal propagation of these trypanosomes. In nature increasing virulence for a vertebrate host is actually an embarrassment to a trypanosome, and yet in the laboratory there is a tendency to regard it rather as a kind of adaptation of the parasite to its host.

An enormous amount of work has been carried out with trypanosomes in European laboratories during the last 20–30 years. Many of the strains used have been atypical derivatives from originals isolated many years previously, and although retaining little or nothing in common with their forebears save a general morphological resemblance, the old specific names are used. Thus we hear of strains of *T. brucei* killing rats in a few days, and stranger still, of a lethal *T. gambiense* that disposed of mice in 2–3 days. Clearly there is little resemblance between such strains and their ancestors fresh from human or ruminant blood; and it is not to be wondered at if confusion has arisen from the continued use of well-known specific names for these curiosities of the laboratory.

It has long been known that a strain of trypanosomes may change materially and sometimes quite quickly when once it is introduced into laboratory rodents. The normal vertebrate hosts of all the tsetse-carried trypanosomes possess one feature in common—namely, a considerable resistance against the protozoon. It is plainly in the interest of the parasite to do as little harm as possible to its host. For example, man's susceptibility to *T. rhodesiense* suggests that he should not be regarded as a natural host of this trypanosome. In nature, until perhaps recent years, it is unlikely that he is of more than secondary

importance as a host. In uncivilised Afric
T. rhodesiense invaded a human communi
either disappeared or the parasite gradually a
itself by assuming a mild *T. gambiense* f
which it had a chance of survival. A wild ve
as susceptible to *T. rhodesiense* as are the lab
rodents would certainly be rapidly extern

the guinea-pig should be avoided as far as poss

It is of course interesting to determine ho
old laboratory derivatives of the human trypano
can retain their power to infect man. B
interest is mainly academic. When once the
has in other respects ceased to be a human p
in the ordinary sense of the term. For ins
Reichenow's Hamburg strain of *T. gam*
isolated from an European in Fernando Po in
was found in Uganda to be still infective to m
subcutaneous inoculation in June, 1935.[3] Bu
same strain had in the meantime become com
non-transmissible by tsetse (*G. morsitans*
G. palpalis). Yet another point. It is easy to
an old laboratory strain of say *T. brucei* res
to drugs, and this resistance, as Yorke an
colleagues have shown, can be greatly enh
without diminution on cyclical passage th
glossina.

Certain strains of *T. gambiense*, on first iso
from man, also possess a considerable resistan
arsenic, and this resistance can presumably
easily be enhanced. It is sometimes assumed
such resistance has been acquired by contact in
earlier passage with arsenical drugs; *but it is eq*
probable that it is a natural feature of certain st
Typically, howe [illegible] is readily sen

resistant have been attended by serious impair
of the transmissibility of the strain by tsetse.
new arsenic-fast variant could not, in other w
develop in the fly. Admittedly this has been obs
so far only twice, once in Nigeria and once in Ug
But it is a point that should be settled, and

for a study of fresh strains and the employment of tsetse. Obviously the development of drug resistance in ordinary arsenic-sensitive *T. gambiense* has no practical significance if at the same time the strains become non-transmissible by glossina.

And here we may digress for a moment on an issue of real importance. There is no denying the danger of producing by improper treatment of native suffering from trypanosomiasis in *G. palpalis* and *tachinoides* areas strains resistant to arsenic. Arsenical drugs are acknowledged as useless in the routine treatment of *T. brucei* or *T. rhodesiense* because both these forms are naturally resistant to therapeutic doses of these drugs. But where *T. gambiense* occurs in its typical form, arsenic is effective because most strains are sensitive to its action. *T. brucei*, *T. rhodesiense*, and *T. gambiense* are, however, all very closely related, and in regions where they all three occur there is likely to be a considerable range of arsenic resistance in the strains isolated from man, for we can no longer confidently believe in hard-and-fast divisions between these three so-called species. In practice the danger can be met, as it is in Uganda, by combining with arsenical treatment a dose or two of Bayer 205. But it may be that this is not the best method and that arsenicals with their attendant dangers should give place altogether to Bayer 205 and its equivalents.

And the moral behind all these reflections? Surely to abandon the study in laboratories the world over of ancient and atypical laboratory strains of the tsetse-carried trypanosomes, and take up in their place samples recently isolated from their natural habitat. Study these until they start degenerating and then scrap them, and so build up a first-hand knowledge of the trypanosomes as they really are in nature. At any rate keep the two classes separate from one another. There is no need to alter the existing nomenclature, but merely our attitude towards old laboratory strains.

One result will be fewer disappointments over the claims made for new trypanocidal drugs, when the time comes to test them out in real life. Among the routine tests applied to trypanosomes should be included, as all important, their behaviour in tsetse. And when once a strain has lost the power to use its normal vector it should no longer be regarded as a true representative of the species from which it was originally derived.

Let us keep the distinction clear between natural and laboratory strains of the pathogenic trypanosomes and exercise due caution in transferring conclusions from one to the other.

CLINICAL AND LABORATORY NOTES

TUBERCULOSIS OF THE NASAL SINUSES TREATED BY IRRADIATION

By W. Annandale Troup, M.C., M.D. St. And.

The forms of irradiation I use in the treatment of sinusitis are: (1) infra-red rays applied locally over the affected antra and sinuses; (2) ultra-violet rays, applied both postnasally and intranasally, by means of quartz applicators attached to the Kromayer mercury-vapour lamp; and (3) ultra-violet rays applied to the whole body by the titanium-alloy arc. The effects arrived at are dilatation of the ostia; establishment of drainage from infected antra and sinuses; increased flow of blood and lymph to the affected areas; increased bactericidal properties in the mucus secretion; regeneration of the mucous membrane and restoration of its normal function; and increase of bodily resisting powers. Success depends on accurate dosage, since varying stimuli evoke varying responses in different cases.

The value of the method is illustrated by the following case.

A man, aged 30, a patient of Dr. E. R. Keeble, was sent to me by Sir Henry Martyn, of Windsor, and first seen on Oct. 8th, 1934. Sir Henry wrote: "Physical signs started in this man's chest when he was fifteen years of age, and were diagnosed as pulmonary phthisis. The symptoms improved and remained quiescent until this summer, when he again had a flare-up with a prolonged burst of temperature. There were physical signs at both bases and at the apex of the left lung. Signs were confirmed by X ray examination, but at no time have tubercle bacilli ever been found in the sputum. The case was referred to me concerning the possibility of sinus infection. Both his antra were dark on transillumination, and on washing them out a clear return was obtained from the right antrum, but a considerable mass of dark translucent white mucus from that on the left. Examination of the washout showed tubercle bacilli in large quantities."

On Sept. 25th the sinuses were examined by Dr. H. K. Graham-Hodgson, who reported that radiography showed polypi in both maxillary antra, and some thickening in the lining membrane of both frontal sinuses (more on right than on left) and of the anterior ethmoidal cells. The right posterior ethmoidal cells and the right sphenoidal sinus were radiologically normal. The left posterior ethmoidal cells and the left sphenoidal sinus showed marked thickening of the lining membranes.

The patient weighed 13 st. 7 lb., and his height was 6 ft. 6 in. He looked debilitated and toxic, and had been running an evening temperature up to 100° F. for three months during which time he had been confined to bed. The joy of life had departed and the mental outlook was without hope.

Irradiation began on Oct. 8th. On Oct. 11th the evening temperature was normal, and the nasal and postnasal discharge much increased. On the 15th his weight was 13 st. 10 lb.; all acute pain had disappeared, and he said that his face no longer felt like a blown-up balloon. On Oct. 24th there was no pain in the occipital region and he was feeling very much better. On the 29th he had gained a further 3 lb. and was able to stoop without giddiness or tightness in the head. On Nov. 5th his weight was 14 st. 2 lb., and Dr. Keeble reported that all active physical signs in the chest have disappeared; by the 11th the evening rise of temperature had altogether ceased; and on Dec. 3rd the weight was 14 st. 6½ lb.

Dr. Graham-Hodgson examined the patient again on Jan. 17th, 1935, and reported that the maxillary antra were now clear-cut and well defined, the opacities previously seen being almost absent. The cloudiness in the frontal sinus had also very largely disappeared. There was still some thickening in the lining membrane in the ethmoidal cells and sphenoidal sinuses, but it was less obvious than before.

On Jan. 22nd the patient was examined by Sir Henry Martyn and the antra washed out. The washings came back quite clear, the fluid was sterile, and no tubercle bacilli were found. By Feb. 21st the weight was 15 st., and on April 5th treatment was discontinued. Dr. Graham-Hodgson's final report stated that there was still some slight cloudiness in the frontal sinus, but no X ray evidence of abnormality in either maxillary antra. There was also some thickening of the lining membranes in the anterior ethmoidal cells on both sides, but the posterior ethmoidal cells were radiologically normal. The lining membrane of the left sphenoidal sinus also showed very slight thickening. Sir Henry Martyn considered the patient fit to continue his duties, which he is now pursuing with greatly increased vigour and perfect health.

This patient had over 60 treatments in all, but it must be remembered that there was a history of over fifteen years, the infection was severe, and his state was drifting from bad to worse. I feel confident that with patience and perseverance many such cases now labelled "hopeless" could not only be relieved of their suffering but returned to the ranks of the healthy.

Sir Henry Martyn adds the following comment.

"The case is interesting both from the unusual character of the sinus infection and from the remarkable response to light therapy. As Dr. Watson-Williams has pointed out, it is common enough to meet with cases erroneously diagnosed as tuberculosis of the lungs, in which no tubercle bacilli have ever been found in the sputum, and which are, in reality, cases of chronic pyogenic infection of the sinuses, but it is certainly unusual to find the exact converse—a case of definite tuberculosis of the lungs, in which no tubercle bacilli had ever been recovered from the sputum, but in which they were present in large numbers in the sinuses. From the point of view of treatment the problem presented by such a case is serious in the extreme. To contemplate operative procedure with such extensive sinus involvement in a patient with advanced pulmonary damage would have been wholly unjustifiable. On the other hand, to anticipate that sanatorium treatment alone would be sufficient to allow a patient to overcome a sinus infection advanced to a degree of actual polypoid degeneration of mucous membrane appeared to be unduly optimistic. In light therapy we appear to have a weapon of the greatest value, and although it would be wrong to generalise upon a single case there would appear to be every justification for a more extended use of this method of treatment."

London.

FREE MELANIN-BEARING CELLS IN ASCITIC FLUID IN DIFFUSE MELANOMATOSIS

By W. R. Snodgrass, M.D., B.Sc., F.R.F.P.S. Glasg.
VISITING PHYSICIAN, SOUTHERN GENERAL HOSPITAL, GLASGOW

A married woman, aged 53, was admitted to Mr. Edington's surgical ward in the Western Infirmary on July 18th, 1931. A pigmented mole was removed from the left hip. Histological examination showed this to be a melanoma. In August, 1933, she developed malaise, discomfort after food, and vomiting.

She was readmitted to Mr. Edington's ward on Sept. 6th. The abdomen was much swollen, and paracentesis yielded, on separate occasions, 280 and 396 ounces of clear ascitic fluid. On Nov. 13th she was transferred to the Southern General Hospital, where paracentesis of the abdomen was performed eleven times, a total of 111¾ pints being withdrawn. She died on June 18th, 1934.

The illness was marked by progressive and extreme emaciation, and latterly irregular masses were palpable in the upper quadrants of the abdomen. At times there were attacks of severe diarrhœa, but the stools showed no blood, pathogenic organisms, or excess of mucus. At no time was the urine abnormally dark in colour. There was no fever.

The unusual feature noted was the presence of free melanin-bearing cells in the ascitic fluid during the last eight paracenteses in the Southern General Hospital. This black material appeared during the last two pints to be withdrawn and increased in amount towards the end of the operation. Palpation of the abdomen greatly increased the quantity of melanin withdrawn.

Paracentesis was performed in the midline above the pubis, and melanotic tumours developed in the sites of the needle tracks. These were bluish-black, firm nodules, well raised above the skin level.

Dr. P. R. Peacock, of the Royal Cancer Hospital, examined the ascitic fluid and reported that such cells as were recognisable appeared to be endothelial cells or phagocytes, probably macrophages, containing pigment which masked their histological features. Two fowls inoculated intramuscularly showed no lesion during several weeks of observation.

At post-mortem examination by Dr. J. N. Wilson, the abdominal viscera were found to be jet black owing to the presence of very numerous melanotic tumours in the omentum, and were matted together. Small pigmented areas were seen in the stomach and small bowel, and parts of the wall of the stomach and small bowel had the consistency of cardboard. The peritoneum and omentum were covered with black nodules. The heart, lungs, kidney, liver, and spleen were not affected. Secondary deposits were found in several ribs, and the mediastinal glands and right submaxillary gland were involved.

Dr. F. E. Reynolds, pathologist to Stobhill Hospital, examined a skin transplantation tumour and reported: "The nodule is lined by a thin layer of epithelium in which there are few 'epithelial pegs'; the deeper cells do not contain an excess of pigment. The neoplasm consists of a number of 'islands' in the subepithelial tissue. One of these is situated in the tissue immediately below the surface epithelium and is not involving the latter structure. The other islands lie deeper. The neoplastic cells are for the most part large and polyhedral and contain a large amount of melanin in the form of fine granules. In certain portions, however, the cells are almost devoid of pigment. Again, examples of small rounded neoplastic cells occur. Both in and around the islands it is clearly demonstrated that local spread of the neoplasm has been along lymphatic vessels and spaces."

The post-mortem findings indicate that the melanoma spread from the left hip by way of the lymphatic vessels accompanying the veins, involving the hypogastric lymph glands first. The freedom from infection of the lungs, heart, kidneys, and spleen suggest that it was never blood-borne. The skin deposits at the site of puncture show local transplantation, which in turn initiated lymphatic extension.

The case is reported because of its rarity. Undoubtedly the intracellular melanin was derived from the peritoneal and omental tumours. In Kaufmann's "Pathology" (1922, p. 1699) it is stated that melanin may occur in transudates but I have found no clinical reference to such a condition published since the war. In a total of 492 cases reported by Boulay (191),[1] Coley and Hoguet (9),[2] Gleave, H. H. (40),[3] Dawson (120),[4] and Butterworth and Klauder (50)[5] no reference is made to it. Incidentally the primary lesion occurred in the lower extremities in 115 out of these 492 cases.

REVIEWS AND NOTICES OF BOOKS

Disorders of the Blood

By LIONEL E. H. WHITBY, C.V.O., M.C., M.D. Cantab., F.R.C.P. Lond., D.P.H., Assistant Pathologist, the Bland-Sutton Institute of Pathology, Middlesex Hospital; and C. J. C. BRITTON, M.D. N.Z., Assistant Pathologist, Christchurch Hospital, New Zealand. London: J. and A. Churchill Ltd. 1935. Pp. 543. 21s.

IN selecting the title of this comprehensive monograph the authors desired to emphasise the rarity of primary disease of the hæmopoietic system and how often changes in the peripheral blood are a symptom of a disease or disorder in some other system of the body. The work contains descriptions of the blood picture to be found in almost all the diseases known to man, from the recognised anæmias and leukæmias to infections and miscellaneous conditions such as allergy, coronary thrombosis, and diabetes. The opening chapter contains a discussion of the origin, development, functions, and fate of the cells of the blood, following on the whole the views of Doan, Sabin, and Cunningham. Three chapters are devoted to the principles and practice of hæmatological diagnosis; the methods of studying red cells, leucocytes, platelets, and the physical and chemical properties of the plasma are discussed in detail with the interpretation to be placed on the results obtained. The causes of anæmia and the nature and mode of action of hæmopoietic substances are analysed, and an ætiological classification of the anæmias is set out. In subsequent chapters the anæmias are discussed under a more clinical grouping, such as the anæmias of pregnancy and the anæmias of infancy and childhood. In all cases an account of the clinical and hæmatological picture is supplied together with a discussion of the pathology, ætiology, diagnosis, and treatment. Though an admirable description of agranulocytic angina is included in the chapter on diseases due to aplasia or hypoplasia of the bone-marrow, the authors point out that in one group of cases at least marrow hyperplasia is characteristic, suggesting that maturation arrest is the fundamental pathology of the condition. In the chapter devoted to the leukæmias modern literature dealing with mononuclear leukæmia is surveyed. This variety of leukæmia is recognised more frequently in America than in Europe. Careful study of the section dealing with hæmo-agglutination and blood transfusion should do much to lessen the fatality from unsatisfactory transfusions. Each chapter is completed by a concise summary and a bibliography. All essential technical methods are fully described in the text, and throughout the monograph knowledge is clearly summarised and presented as far as possible in tabular form. The book is well illustrated with graphs and coloured plates both of macroscopic appearances of the bone-marrow and of blood films stained presumably by Leishman's stain though no indication of the method employed nor of the degree of magnification is given. The research worker in hæmatology may regret certain rather uncritical statements; for instance, in a discussion of the value of the reticulocyte count the unqualified remark that "if a reticulocyte crisis occurs it can be assumed that the treatment will be effective." Unfortunately work which was summarised in the special article by Minot and Castle which appeared in our columns last month[1] has shown that there are many non-specific substances such as arsenic and certain protein derivations which when given to patients with pernicious anæmia may cause an output of reticulocytes but no further rise in red cells or hæmoglobin; while the exact interpretation of the response in any case depends on a careful evaluation of many variable factors which are not discussed by Whitby and Britton.

This monograph should prove of great value to students and practitioners who need a concise summary of the ever-increasing literature on hæmatology, much of which is of immediate clinical importance. They will find in this work little unnecessary theory and much practical information set out clearly and succinctly.

Radiological Atlas of Chronic Rheumatic Arthritis (Hand)

By S. GILBERT SCOTT, M.R.C.S., L.R.C.P., D.M.R. & E. Camb., Honorary Radiologist to the British Red Cross Clinic for Rheumatic Diseases, Regent's Park, and to the Charterhouse Rheumatism Clinic; Consulting Radiologist to the London Hospital. London: Humphrey Milford. Oxford University Press. 1935. Pp. 76. 30 plates. 25s.

THIS important monograph should pave the way to a better understanding and treatment of "rheumatism." Dr. Gilbert Scott makes no claim to be an authority on rheumatism, but after an exceptionally wide general experience he has in recent years studied with an open mind a wealth of clinical material passing through the British Red Cross rheumatism clinic and has drawn from this study conclusions of great practical value. All may not agree with him when he attributes the failure of workers in the past, notably Strangeways, to elucidate the problems of rheumatic conditions mainly to their unquestioning acceptance of the clinical diagnosis. There is much in his claim that the clinical diagnosis of these conditions is unreliable taken alone, and that the only accurate method of diagnosis is by the radiological examination, but most clinicians would maintain that both methods must be used together. Dr. Scott uses the hand as "the visiting card of the rheumatic patient." He classifies his cases on a radiological basis, and claims that nearly all fall under four well-defined headings. Doubtless this simple classification is open to criticism, but it serves its purpose and is, at least, a reasonable foundation. The 30 radiograms are, of course, so well reproduced as to show clearly the changes described.

Chronic Nasal Sinusitis and its Relation to Mental Disorder

By F. A. PICKWORTH, M.B., B.S. London: H. K. Lewis and Co., Ltd. 1935. Pp. 156. 16s.

THE first element in the title of this book receives much more attention than the second; it may indeed be questioned whether any essential connexion between the two follows from the evidence so laboriously collected and here so fully presented. The finding of sinusitis in patients who died in mental hospitals, often after many years of institutional life, cannot be taken as ætiologically significant in the absence of control data. Dr. Pickworth has an ingenious theory about the vascular happenings which follow on chronic nasal sinusitis and are responsible for physical changes of the brain tissue. The earlier chapters of the book are devoted to the anatomical, physiological, and pathological basis for this view; there are then three chapters dealing, respectively, with nasal sinusitis in general medicine, the pathology of mental disorder and defect, and the relation of nasal sinusitis to cerebral pathology and mental disorder. Notes of special cases and some methods of investigation are appended. The detailed observations will be critically examined both by the rhinologist and the psychiatrist. The latter may find it difficult to agree that loss of brain substance from severe and prolonged functional ischæmia leads to a spreading of ungoverned nerve impulses and so to abnormal conduct, or that hysteria should be treated as a medical disease due to minute focal brain lesions. The illustrations in the book are from original specimens and well produced.

[1] THE LANCET, August 10th, 1935, p. 319.

The Osteopathic Lesion

By GEORGE MACDONALD, M.B., Ch.B. Edin., D.O. Kirksville, U.S.A., and W. HARGRAVE-WILSON, D.O. London: William Heinemann Ltd. 1935. Pp. 141. 7*s.* 6*d.*

THIS book is of value as a contribution to the discussion of the claims of osteopathy, which have recently aroused so much public interest, in that the authors state precisely what they believe the osteopathic lesion to be. In order to make their meaning clearer they have chosen to concentrate upon an osteopathic lesion of the joints between the fifth and sixth dorsal vertebræ; they define the lesion as an acute or chronic joint strain which leads to local, peripheral, visceral, and general effects. Particular stress is laid upon the visceral changes which are supposed to be produced by nervous impulses arising in the neighbourhood of the strained joint, passing to the spinal cord, and reaching the viscera along sympathetic efferents—the so-called somatico-visceral reflex. They claim that Mackenzie's views on the viscero-motor reflexes harmonise with osteopathic theory, though they admit that in the reflex path which he described the impulses travelled in the opposite direction. It must also be remembered that Mackenzie was able to bring forward sound evidence that a viscus is capable of providing an adequate stimulus to excite the reflex, whereas the theory that a strained joint can provide a stimulus is conjectural, the authors' suggestion being that, "because of the popularity at the present moment of physiological chemistry and hydrogen-ion concentration in medical research," the possibility that biochemical changes in and around the osteopathic lesion may be of ætiological significance cannot be dismissed. They are satisfied, however, that it would be only reasonable, even without any evidence, to assume that it is possible for a joint strain to give rise to such reflex effects in the viscera, and they go so far as to hint that the areas of tenderness over the dorsal spine described by Mackenzie in cases of gastric disease were in reality the local evidence of the osteopathic lesion to which the changes in the stomach were secondary.

Dr. Macdonald and his collaborator state that the anatomy, physiology, and all the basic sciences taught in osteopathic institutions are exactly the same as those taught in medical institutions. Though this may be so, there are certainly profound differences between these sciences as taught in the medical schools and the references to them which appear in this book. It would be difficult, for instance, to explain on physiological grounds the close relationship between the cilio-spinal centre and the centre of life, or why a sense of general well-being should depend upon the integrity of the second dorsal segment, or why the proximity of the spinal muscles to the central nervous system should account for the particularly marked tension of these muscles which is alleged to result from mental anxiety. The statement that it may well be an osteopathic lesion of the upper dorsal spine which predisposes the upper lobe of the lung to tuberculous infection is scarcely to be taken seriously when one reads in the next sentence that a large number of suspected tuberculous infections of the lungs prove on radiological examination to be nothing more than upper dorsal scoliosis.

The alleged effects of the osteopathic lesion are traced step by step from disturbances of the neighbouring organs to malfunction of the ductless glands and to reduction of the general resistance of the body to infection, and finally we are guided to the inevitable conclusion that the great possibilities of osteopathy lie in preventive medicine, though it is admitted that there are a few diseases which are sufficiently potent in themselves to cause illness even in an osteopathically sound body. Such extravagant ideas do not pervade the whole book, which is characterised rather by the modesty of the claims made by the authors for the healing power of osteopathic manipulation. They consider that this form of treatment is not suitable for cases of established disease, but that it is indicated particularly when symptoms are due merely to some disturbance of visceral function, or to neurasthenia and nervous exhaustion. It is a book which should be read by any medical man who wishes to judge for himself whether the osteopathic concept is founded on scientific fact.

Dorland's Medical Dictionary

The American Illustrated Medical Dictionary. Seventeenth edition. By W. A. NEWMAN DORLAND, M.D., F.A.C.S. With the collaboration of E. C. L. MILLER, M.D. Lond. London: W. B. Saunders Co., Ltd. 1935. Pp. 1573. 30*s.*, or with thumb index, 32*s.* 6*d.*

IT is not three years since we reviewed the sixteenth edition of this dictionary. The preface tells us that during this time a large corps of collaborators have scrutinised every page, editing the whole matter and adding several thousand new definitions. There are 80 more pages, but the bulk of the volume is certainly not greater and the price is 5*s.* less. It is hardly necessary to tell our readers about the contents of so well known a volume; its completeness is such that it is now something like a treasure hunt to find any missing words. But Dorland still knows nothing of the Higginson who invented a syringe, although we can now find Peter Chamberlen who invented the forceps; there is a convenient single word to express the belief that the world exists only in the mind of the philosophising individual and that word is not in Dorland. The second initial of the Swedish physiologist whose memory is perpetuated in the wool test is not C., the name is Frithiof. But the other minutiæ we had reserved for this occasion have been picked up in the really admirable revision. We would only ask the editors what has happened to the x of thorax in the word "thoracentesis," and whether the portrait on p. 620 is that of Wilhelm His senior or junior. The dictionary, as we have said before, is a masterpiece of legible compression.

THE LANCET

LONDON: SATURDAY, SEPTEMBER 21, 1935

A HOSPITAL INSURANCE SYSTEM

No better start can be offered to a gathering of professional men of widely different outlook, habitat, and experience than a provocative address covering interests common to them all. During the course of his survey of hospital problems, published in last week's *British Medical Journal*, Sir JAMES BARRETT gave to well-worn themes a new orientation, and to prickly issues that firm grasp which mitigates the effect of their sting from a painful eruption to a mild titillation by no means disagreeable. It is not customary for the British Medical Association to discuss in public the president's address, but one can imagine the members congregating in small groups as they left the Melbourne Town Hall eagerly debating such questions as the source of capital and revenue of hospitals in different parts of the Empire; the optimal size of hospitals anywhere; the remuneration of the medical staff—whether in prestige and experience, or in cash; the widespread exploitation of student labour in the routine nursing of hospital patients; and the far-reaching development of contributory schemes in Victoria during the last 25 years. It was with an account of this last adventure in hospital insurance systems that Sir JAMES opened his survey, and it is not unreasonable to suppose that its success has influenced his outlook on the economics of hospital provision elsewhere.

It appears that in 1911, under the auspices of the Victoria Bush Nursing Association, one trained nurse was established after many difficulties at Beech Forest, the residents undertaking to pay her salary. In two years' time there were 13 such nurses. At first the money for their salaries was raised by local subscription, but the varying amounts contributed by residents caused trouble, and it was decided that all contributors should pay the same sum and should be entitled to nursing care at need without further charge. Next came the problem of housing the nurses, and it was found that the privacy and convenience of both nurse and patient was best assured by the renting of small cottages for this purpose. The supervision of centres great distances apart became impossible as an honorary service, and in 1913 a superintendent was appointed with the aid of the Walter and Eliza Hall trust. The movement grew until in 1921 there were 33 centres; then small cottage hospitals began to be established by generous benefactors, and to these were transferred the payments under the contributory scheme for nursing. Contributors became entitled to hospital and nursing attention for themselves and their dependants up to a certain age, at the cost of about £2 2*s*. per week over and above their annual subscriptions, making their own arrangements with their medical attendants. In 1926 the Edward Wilson trust decided to establish an ambulance service on a similar basis to the nursing association—that is, to be self-supporting after the initial gift. Now, in 1935, there are in Victoria —a State with an area of 88,000 square miles and a population of 1,800,000—69 centres maintained on a contributory basis, served by 22 ambulances; 45 of the centres are hospitals with an aggregate of 416 beds. These hospitals receive no State aid for construction or, except in six special cases, for maintenance. They must maintain themselves or close; and so far none has closed. They are staffed entirely by well-paid trained nurses, and are said by Sir JAMES BARRETT to provide the cheapest hospital accommodation in the State. He claims that a great improvement in medical practice has resulted from the provision of suitable buildings and highly trained nurses in country districts. It is noteworthy that all the doctors who treat patients in these hospitals become ex-officio members of the committee of management, and that the hospitals, in addition to their usual functions, provide centres for welfare work and for the medical inspection of school-children. The system works smoothly and efficiently.

Far less satisfactory from the financial point of view is the position of the so-called public hospitals in Victoria. These are maintained by voluntary contributions, by Government subsidy, and by patients' contributions, but are not under direct Government control, being administered by honorary committees. Up to about 1900 this arrangement is said to have worked tolerably well but since then conditions have changed. The total income from all sources has increased fourfold but has, of course, been matched by the expenditure. The number of patients desiring treatment has increased nearly fivefold, though the population of the State is only about 50 per cent. greater than it was. In 1900 the number of patients treated by public hospitals was 7·2 per cent. of the population; in 1934 it was 17·4 per cent. Sir JAMES BARRETT holds strongly that the main problem of finding and financing hospital beds in sufficient numbers arises from the fact that the sick population of every class has become more hospital-minded. It is with the future of these public hospitals that his address is largely concerned. His bias is clearly towards their maintenance as far as possible on a voluntary basis, aided by Government subsidy but managed as hitherto by honorary committees. Some of the arguments wherewith he supports his thesis may require closer examination, but they lead him to such interesting by-ways that none will reproach him for straying from the strictly logical path. Our own quarrel would be not so much with the deduction he draws from premises not always clearly stated as with any attempt to discuss such problems as the optimal size of a hospital from the purely financial aspect. This is a matter that must depend on such factors as local needs, the site available and its accessibility, and the proposed construction of the hospital.

For example, the transit of personnel and material between departments, which is one of the causes of extra expenditure in a very large hospital, is minimised if the hospital is built on a vertical rather than on a horizontal plan; and the relative cheapness of construction and maintenance of a very small hospital often implies less efficient medical service, especially in the lack of special diagnostic departments. The wide variation of standards is illustrated by the statement attributed by Sir James to the staff of a Bush nursing hospital of 30 beds, that not more than 4 per cent. of the patients require a pathologist. The primary need, however, in isolated districts is adequate clinical supervision and nursing care, and that is clearly available in the hospitals under the contributory scheme of the Victoria Bush Nursing Association. Sir James Barrett's main theme, that in all countries institutional rather than domiciliary treatment is being demanded by an increasing section of the public and will have to be supplied, is not likely to be disputed, and his exposition of a hospital insurance system so well adapted to the needs of the country it serves will command attention.

THE CARE OF THE MENTALLY DEFECTIVE

Public interest is easier to arouse in curable disease than in disorders which are apparently not amenable to treatment, and this no doubt has been one reason why mental defect has been largely left to philanthropy. Another reason for its neglect is the stigma of its supposed relation to insanity. But more and more has mental deficiency been forced on public notice as a problem in sociology by the Brock report and by the suspicion that a considerable proportion of crime is committed by those suffering from mental defect. What has not kept pace with this realisation is the effort to solve the problem. It is only slowly being grasped that much less spectacular measures than eugenic sterilisation or the intelligence testing of offenders can be undertaken by authorities which have the encouragement of informed public opinion. An important section of the Board of Control's report for 1934, a summary of which is given on p. 685, contains some record both of the activities of philanthropic bodies and of the tardy appreciation by public bodies of what can be done.

Only half the estimated probable number of defectives are notified, and of these rather less than half are in institutions. Something of the discrepancy which exists may be gauged from the fact that of the small number of criminals during 1934 who were proved to be defective almost three-quarters had not attended a special school at all, a figure closely resembling the Wood Committee's estimate that 77 per cent. of feeble-minded children are educated in ordinary elementary schools. Such a result can only arise from the fact that the provision of special schools remains too small; numbers of children who swell the overcrowded elementary school classes are incapable of profiting by the teaching provided. These facts are appreciated by education committees. But local authorities have no legal responsibility for the defective child between the ages of 14 and 16, and although this is a state of affairs that cannot last much longer, the knowledge that such a gap exists has played into the hands of authorities which shirk the care of defectives. The medical practitioner meets many situations in which a knowledge of the social implications of mental defect is of value. He is not limited to the thankless task of seeing that the unfortunate child is properly notified. Many defectives can be placed under guardianship in suitable homes, where they have a chance of doing some kind of manual wor for which they are fitted. In Scotland, wher guardianship is more generally used, the remova of defectives from home—often, alas, the environment most unsuitable for them—has had a beneficia effect. There are many cottage homes in th country which would welcome a paying guest o this kind if the medical man were to suggest it There is work to be done both for defective children and adults. Special schools offer an opportunity of teaching posts to those who are better suited for this specialised work than for more routine teaching. Medical practitioners are likely to know the kind of women who, making hard weather of ordinary teaching, might flourish teaching the educable defective. Day centres and clubs, now being opened in various places, afford scope for many who would fight shy of more obvious philanthropy. At these centres defectives who live at home, or are under guardianship, can attend and do simple but useful work. Women applying for such posts need not have had previous experience in schools, though interest in Froebel method or its equivalent is of value. The extent of all these opportunities is outlined in a pamphlet issued by the Central Association for Mental Welfare, 24, Buckingham Palace-road, London, S.W.1.

Medical influence in these matters need not be restricted to the private contact between doctor and patient. Medical officials of the public bodies can only work for reform if the elected representatives on these bodies are pressing for progress. Whether as a member of the public health committee or as a magistrate the medical man's opportunities of stimulating interest in the care of the mentally deficient are considerable. There is no obvious reason why England should lag behind Scotland in the guardianship of mental defect, or why freer use should not be made of the services offered by the Central Association or the Guardianship Society. There are bodies whose title suggests more exciting efforts, but few which are working so quietly along progressive lines.

PERSONALITY AND AGE

Personality is the product of a large number of dependent variables every one of which must be studied in relation to the independent variable, age. It is fortunate that, in this country at any rate, documentary evidence is available for determining age with scientific accuracy, fortunate since in its absence there would be little if any proof of age which would be accepted as conclusive in medical jurisprudence. For age as represented by solar time may be a very different thing from age in the biological sense. A person may be 30 years of *age* but 60 years *old* when judged by physical, physiological, or psychological criteria; and the converse is equally true. The tendency to change with advancing age is worthy of investigation. How frequently we fail to appreciate the significance of tendencies is illustrated by the many attempts to elicit the secret of longevity from the behaviour of an individual centenarian. The statements of the celebrated Brighton twins may be recalled. One attributed his health and longevity to his being a non-smoker and a total abstainer; the other was equally confident that his condition resulted from his lifelong generous indulgence in both alcohol and tobacco. Such was the leit-motif of the presidential address given by Mr. LL. WYNN-JONES, Ph.D., to the psychological section of the British Association at Norwich. He is careful to point out the difficulty of distinguishing between the senile and the pathological. A person who is as mentally alert at 90 as he was at 50 would be abnormal, but certainly not pathological. If he showed the mental deterioration customary to age it should more properly be regarded as a senile than a pathological change. In the individual personality there may be both pathological and senile changes which cause a deterioration of function long before the total personality has attained its maximum development and physiological perfection. There are functions which improve with age at least to middle life, which is admittedly a question-begging qualification; others which deteriorate with age; and still others which are largely independent of age. Dr. WYNN-JONES refers to the plebiscite invited in Germany a few years ago to enumerate the subjective sensations of becoming old. Analyses of the reports showed that the average age was 49, but individual variations were very wide, indeed from 18 to 82. As might have been expected, some laid greater stress on bodily than on mental signs; others did precisely the opposite.

In his "Adult Learning" (1928) E. L. THORNDIKE published a study of the changes in the ability to learn from age 15 to age 45. He concluded that nobody under 45 should restrain himself from trying to learn anything because of a belief that he is too old to learn. "If he fails in learning it, inability directly due to age will very rarely if ever be the reason." The reason is more commonly a constitutional inferiority to learn that particular thing or the lack of a sufficiently strong desire to encourage adequate application. THORNDIKE's conclusions are naturally important in respect to schemes for adult education. On the average, visual acuity, which is probably the first physiological function to deteriorate with age, becomes at 50 sufficiently serious to handicap the individual in occupations where visual requirements are exacting. But in a test of reaction speed the average man of 80 is only 50 per cent. slower than the average man in his prime, and even the latter is less speedy than some men of 80. Industrial accidents decrease with increasing age from the greater experience and caution of the older workers. As a contrast, pedestrian accidents are far greater over 65. This of course is only to be expected when one considers the disadvantageous circumstances which come into play—increase in weight, decrease in agility and speed, impairment of sensory acuity, and a variety of senile effects on mentality. W. R. MILES has pointed out[1] that intellectual abilities, as measured by tests of memory and of intelligence, show a relatively small deterioration: and since differences between individuals at the older ages are often quite marked, other factors are probably more weighty than age. Prof. CHARLOTTE BÜHLER[2] singled out the importance of age in athleticism, utilising the records of 1930 as criteria of maximal motor abilities. It appeared that activities which demanded a maximum of expenditure of energy were best demonstrated by the youngest—e.g., the champion sprinter's age was 23·5 years. When greater economy of effort and demands of technique came into coöperation, the age of the champions became progressively older—e.g., the distance runner, 25·6 years; the tennis player 28·5 years; the polo player up to 50.

Dr. WYNN-JONES, in referring to Prof. BÜHLER's conclusions, has extended the analysis to two typical British sports, cricket and golf. He observes that when the highest standard is demanded—batsmen who have exceeded three thousand runs in a season—the median age is 34·5 years, and that in golf the 37 open champions since 1894 showed a median age of 31 years, the extremes being 23 and 44. Dr. ADOLPHE ABRAHAMS has published some observations which bear upon this aspect of age in athletics. The tendency, he believes, is to accept too readily as inevitable a reduction of activity through increasing age. He has supplied examples of athletic improvement long past the time when it is generally looked for, and he attributes such improvement to increasing experience: not merely the acquisition of technique or of judgment in employing the physical resources to the best advantage, but a sort of individual cell education automatically acquired as the result of continued training and automatically utilised. Dr. WYNN-JONES concludes with the reminder that not only during childhood and adolescence, but throughout the life span, age as one of the primordial potencies should be studied more systematically. The relative importance of the various traits at different stages of life has a bearing upon such vital problems as the school-leaving age, the age allowance for scholarship candidates for the universities, and the necessity to ascertain in industry how far the handicaps of the older workers are due to their own physiological, mental, or vocational disabilities and how far to the age prejudice of employers.

ANNOTATIONS

PLEURAL AND PULMONARY SEPSIS

IN his Lettsomian lectures to the Medical Society of London, which have now been published in the transactions, Mr. J. E. H. Roberts covers the whole field of the surgery of pleural and pulmonary infections. The general reader will perhaps be most interested in the sections which deal with the septic infections of the lungs and pleura—bronchiectasis, pulmonary abscess, and empyema—for these are emergencies of medical practice which concern the general practitioner at least as closely as they do the workers in special departments. The adequate treatment of bronchiectasis, as Mr. Roberts rightly insists, demands the collaboration of physician and surgeon. The patient depends upon the former for diagnosis at a stage when surgery can still offer a hope of cure. It is no longer necessary to wait until gushes of stinking sputum at stated hours, clubbed fingers, and physical signs of expectoration bring melancholy proof of incurable disease. The injection of lipiodol as a preliminary to X ray examination of the bronchial tree is seldom necessary in such cases and may indeed be undesirable. But in the exploration of lungs damaged by pneumonia, in the investigation of obscure cases of chronic cough or hæmoptysis, lipiodol will often clarify the clinical picture and point the way to relief. In the same field diagnostic bronchoscopy has made notable advances. Early diagnosis in this disease as in most diseases implies the possibility of cure. Here lobectomy has achieved its most notable triumphs. The experience of Mr. Roberts enables him to support the teaching that this hazardous operation is less dangerous in early life than it is at a later age. As youthful sufferers from infected bronchiectasis, one of the most loathsome of all diseases, have hitherto been condemned to early death, it seems likely that this operation will be more frequently undertaken. The operative mortality, estimated at under 10 per cent., is a slight risk compared with that of the untreated disease. For the relief of patients whom surgery cannot help the system of postural drainage, advocated by Mr. H. P. Nelson, based upon the anatomy of the bronchial tree will be found far more efficient than the traditional bedside tipping and the creosote chamber, which was at best a clumsy and relatively ineffective method of inducing cough and expectoration.

In the treatment of empyema a tendency to postpone or to endeavour to avoid operation has been noticed since the discovery of the heavy death-rate among influenza patients suffering from watery empyemata and submitted to early operation. The finding of pus in the pleural cavity is no longer regarded as an indication for an emergency operation. Patients are now sometimes left soaking in their own pus for days until a series of test-tubes indicate that safety has at last been attained and the pleura may be opened without the risk of mediastinal flutter or other imagined evils. But whether pus in the pleura is of syn-pneumonic or meta-pneumonic origin, whether we have to deal with an empyema involving the whole pleural space or a pleural abscess limited by adhesions, the principles of treatment remain the same. It is only their application that must be altered. Pus must be removed and the sooner it is removed the better; the cavity must be obliterated, and any delay in its closure may result in a chronic empyema; the function of the underlying lung must be restored, and the earlier it is restored the more complete will be its restitution. Repeated aspirations are seldom curative and they are disturbing to the patient; they diminish but do not abolish toxæmia. Mr. Roberts advocates a single aspiration as a preliminary measure when the mediastinum is mobile, but for subsequent drainage he recommends an intercostal catheter and closed drainage system. There is general agreement that a closed drainage system, preferably with some form of suction, should be used whenever an empyema in the acute or early chronic stage is treated by thoracotomy and rib resection. The considerable number of cases of chronic empyema still encountered proves that the early treatment of empyema is often imperfect. Yet the principles upon which treatment should be founded are easy to understand, the technique of their application is simple, and the results of such treatment entirely satisfactory. It is neither to the credit of medicine nor surgery that two thousand years after the death of Hippocrates the treatment of empyema should so often be undertaken in ignorance and conducted in a perfunctory manner for which the patient has to pay, often in years of suffering and not seldom in permanent invalidity.

ACCIDENTS AND THE MORTALITY OF YOUNG ADULTS

A CURIOUS feature has been observed in German and French life tables which is absent from the corresponding English tables: the probability of dying in early adult male life (between ages 20 and 30) does not rise steadily with age but for a few years of life shows a slight decline. For instance, in Germany, in 1924–26, the mortality figure at age 22 was 457 per 100,000, while at age 29 it was only 404; the corresponding figures for England and Wales, in 1920–22, were 374 and 418. In the English figures there is an unbroken rise with advancing age, in the German ones a temporary improvement in the mortality experience, an improvement which is also absent in Germany and France from the female experience. This improvement amongst the males was attributed by Otto von Schjerning, in his book, "Sanitätsstatistische Betrachtungen über Volk und Heer" (1910), to the favourable influence of compulsory military service, an advantage which young adult Englishmen do not enjoy. The validity of this explanation is somewhat shaken by the results of an excellent statistical study published by W. J. Martin in the current number of the *Journal of Hygiene*. In life tables constructed on the census population of England and Wales in 1931 and the deaths registered in 1930–32, he finds that a similar course of mortality has now appeared in this country. As conscription cannot be invoked as an explanation he turns to the different causes of death in search of the responsible factor. The only two found to exhibit a decline in the mortality-rates between the ages of 24 and 27 are tuberculosis and accidents. The greater decline with age is shown by accidents, which have become proportionately much more important as a cause of death between 1920 and 1932; tuberculosis, on the other hand, has become proportionately less important. The new indentation in the English mortality curve for males is clearly derived from accidents, and excluding them the mortality curves rises steadily with age. The mortality of females from accidents follows much the same course, but with them such causes of death form in young adult life only about 5 per cent. of the deaths from all causes, whereas for males they accounted in 1930–32 for 20 per cent. of the total mortality at ages 19–23. With females, therefore, the contribution of accidents is not sufficient to change the general trend of mortality with age; with males it is amply sufficient. Subdivision of accidents into type shows that the mortality from every type except road transport is, at ages 20–25, at a lower level in 1930–32 than in 1920–22. Road accidents have increased at these ages by 450 per cent. in ten years, and accounted for more deaths in 1930–32 than did all forms of accidents in 1920–22.

THE RADIUM BEAM

ON another page Mr. Stanford Cade and Mr. F. M. Allchin describe the combined treatment of hypopharyngeal cancer with X rays and radium, suggesting that such combined treatment of extrinsic laryngeal cancer by irradiation with different wave-lengths may increase the radio-sensitivity of the tumour and so lead to retrogression of the disease. This treatment they claim is safe as compared with more intensive methods. The quantity of radium used was two grammes at a distance of 6–7 cm. from the skin, each patient receiving two treatments of 50 minutes each in the twenty-four hours, five days a week for six or seven weeks. The authors think that two grammes of radium may not be the best possible quantity for this purpose and state their intention of increasing the quantity as opportunity arises. It is announced that a new "bomb" containing four grammes of radium is to be assembled and tested in the workshop of the Westminster Hospital radium annexe at Hampstead. In this bomb the hollow globe will probably consist of a new tungsten alloy one and a half times the density of lead, with a gold or platinum collar at the outlet, by means of which the gamma rays will be more effectively prevented from spreading, the size of the bomb remaining unchanged. With the new apparatus radium beam treatment will be applied at a greater skin distance with the result that a more effective dose can be given at a greater depth below the surface. Minor improvements in the suspension of the bomb will avoid the necessity of adjusting the distance of the radium from the patient by raising or lowering the radium container. The present two-gramme bomb is at present continuously in use at the annexe for five days a week with three shifts of operators, two days of the week-end being reserved for experimental work. It will be a satisfaction to all concerned when the new building in Horseferry-road, with its ample allotment of space for radium and cancer work, will bring this work again into close relation with the clinical activities of Westminster Hospital.

TOXIC ACTION OF VOLATILE SOLVENTS

IN recent years the industrial use of volatile solvents has increased, especially in the processes involved in cellulose spraying, in the rubber and artificial silk industries, and in the dry cleaning of clothes. It has long been known that inhalation of the vapour of many of these may have serious toxic effects. Thus chronic benzol poisoning is characterised by progressive anæmia with leucopenia and hæmorrhages; many of the chlorinated hydrocarbons of the aliphatic series produce severe and often fatal hepatic and renal damage. Inhaled in high concentration these vapours produce general anæsthesia, often with convulsions and other toxic effects on the higher centres. Dr. L. Dautrebande[1] has directed his attention to a different type of action, namely, that on the blood-vessels, the solvents investigated being benzol, petroleum ether (the lower boiling fractions present in petrol), and amyl acetate. After one minute's inhalation by dogs of air loaded with either benzol or petroleum ether there is not only a fall in blood pressure, but the occlusion of the carotid sinuses which normally gives a large rise in pressure is now without effect. Amyl acetate has no such action at ordinary temperatures, but if the inspired air is warmed to above 28° C. the same phenomena are observed. The normal response to carotid sinus occlusion returns about two minutes after withdrawal of the vapour. By studying the effect of inhalation of these substances before and after the administration of a number of drugs acting on different points of the vasomotor system, it is concluded that their action is due to a direct effect on the walls of the blood-vessels. This view is confirmed by the fact that all three solvents have a direct paralysing effect on isolated smooth muscle. Thus it is shown that saturated solutions inhibit the contractions of the frog's heart, the rabbit's intestine, the pig's ureter, and the virgin rabbit's uterus. Evidence is also adduced to show that benzol and petroleum ether when inhaled have a direct toxic effect on the heart; in fact, if benzol and adrenaline are administered simultaneously, death often results from ventricular fibrillation, benzol in this respect resembling chloroform. Dautrebande considers his results of significance for industrial toxicology, and it will certainly be of interest to see if similar phenomena can be detected in man now that attention has been drawn to them. The vasomotor paralysis may well explain the syncope which occurs in acute poisoning with these substances. It is unlikely, however, that these effects are related in any way to the serious damage to the hæmopoietic system which occurs in chronic benzol and petroleum poisoning.

PRACTICAL LESSONS FROM IRRADIATION OF BODO CAUDATUS

THE effect of gamma ray irradiation upon the growth of the protozoon *Bodo caudatus* has been the subject of prolonged and careful study over a considerable period by Miss Muriel Robertson, D.Sc., and her collaborators at the Lister Institute, and in two recent publications the results obtained have been summarised.[1 2] It is the non-necrotic effects of gamma rays in restraining growth that have been studied. The organisms were not killed by the amount of radium used; their food-supply was unaffected by the irradiation and the reactions in regard to rates of growth of the successive generations of cells, their size and physiological reactions could be studied in comparison with those of controls under normal conditions.

It was found that the cells of less than a certain age at the moment of exposure were greatly delayed in entering into division, so that the increase in numbers could be restrained till it equalled only 20 to 30 per cent. of the normal growth. This extreme restraint of the multiplication was an expression of the reaction of sensitive cells exposed for the first time in their cycle of growth from their emergence at division of the parent to their maturity or moment of ripeness for division. Upon further prolongation of the irradiation the growing cultures showed a recovery in rate of multiplication and the subsequent passage through this cycle (that is the production of the second and later generations) in the presence of the radium occupied a lesser time than the first. Expressed in hours, it was shown that irradiations of two hours and less were of little effect, exposures of 4 to 8 hours produced the greatest actual check in the multiplication, while those lasting for periods of from 10 to 22 hours which last was the limit of the experiments, showed growth varying only within narrow limits and averaging about 60 per cent. of the normal computed over the whole period. There was no further summation of effect with the increasing duration of the exposure after the tenth hour, which coincided with the evolution of the second generation produced during the irradiation. The evolution of the cultures in the presence of the radium was characterised by an enhanced size in the irradiated cells in comparison with the normal. The physiological reaction to the radium which was correlated with this larger size has been studied by Lawrie and Robertson.[1] They found that the very short irradiations of 2 to 3 hours were marked by a reduction in the nitrogen metabolism of the irradiated cells as judged by the production of ammonia; after about 3 to 4 hours on the radium plaque the ratio between the normal and irradiated in this respect lay either slightly below or approached unity. From 5 hours' however to somewhere about 9 hours' exposure the nitrogen metabolism as expressed per bodo was definitely greater, actually increasing to about double that of the normal; the ratio finally settling for irradiations of longer duration (10 to 22 hours) at about 42 per cent. above the normal. Upon removal from the radium, an effectively irradiated culture of *Bodo caudatus* after a period of time begins to accelerate in the rate of multiplication above the normal until if sufficient time is allowed the numbers of cells on the released plate comes to equal those in the normal control. During this compensatory process the enhanced size produced by growth in the presence of radium returned to the normal. There was no radium fastness and re-irradiations were always effective in some degree. The cells having approached the normal again had to be reconditioned if they were exposed again and went through the check in rate and rise in size as in a first exposure. In so far as they had not returned to the normal during the released period the power to evince the rise in rate of increase which was now imminent was held in check by the re-exposure, the multiplication was kept at the uncompensated level, or was further depressed.

[1] Lawrie, N. R., and Robertson, M.: Biochem. Jour., 1935, xxix., 1017.

[2] Robertson, M.: Brit. Jour. Radiol., 1935, viii., 502 and 570.

These results may well have a practical application in therapeutic irradiation, but from the medical standpoint they are minimal effects, since no necrosis was induced and there was no change in the value of the ample food-supply. The occurrence of a particularly sensitive period in the life of the growing cell seems once again to have been demonstrated, and the importance of considering the growth of cells in relation to the succession of generations emerges clearly. Thus a single effective irradiation appears to be one that lasts over rather more than one normal generation time of the growing cells. Exposures of less than 2/5 of the generation time were practically speaking ineffective. The cells of the second generation produced during a continuous exposure show definite recovery in the rate of multiplication in these non-necrotic irradiations, but they are forced into a larger size and show a higher nitrogen metabolism. Under the conditions of the practical irradiation of tumours the cells might, without necrotic changes actually being produced, be rendered unable to respond to the exacting physiological demands of growth in the presence of radium. It must also be added that tissue cells, being more sensitive than protozoa, are liable also to irreversible injuries which do not come into consideration in these studies. The absence of further summation of effect with increase in the duration of the exposure beyond that achieved at the end of the second generation of cells in continuous irradiation is a point of practical importance. Taken in conjunction with the interesting fact that after a fully effective irradiation it requires the period of one to one and a half generations of growth after the removal of the radium before the compensatory acceleration of growth sets in in these uninjured organisms, it shows that long intermissions in exposure may be inserted without loss of total effect. This was tested experimentally and the effect of properly spaced interrupted irradiations was found to lie within the limits of continuous irradiations over the whole experimental period of four to four and a half generations (22 hours). As further points of practical interest it may be noted that there is no evidence of any primary stimulation of growth in these non-necrotic irradiations. There is also no sign of radium fastness in the sense of acquired resistance or insensitiveness due to previous exposure. The organisms which showed temporary adaptation to radium by the recovery of their rate of multiplication in the second and subsequent generations of growth in a continuous exposure returned to normal upon the elapse of from 1·7 to 3 generations of growth in the absence of radium, and were then exactly as sensitive as on the first occasion. The adaptation was a purely physiological one made appreciable by the enhanced size and raised metabolism which seemed to be the necessary condition of growth in the presence of gamma irradiation. It is again noticeable here that the cultures were more sensitive to the effects of irradiation in periods of rapid growth and oxygen uptake than in periods of lesser activity in these respects.

A FRENCH SANATORIUM VILLAGE

AT the end of the war France was faced with a serious deficiency in sanatorium accommodation for middle-class patients. A depreciated currency made treatment in Switzerland possible only for the wealthy and the French Alps did not at that time provide an adequate substitute. To meet this deficiency the "Association philanthropique des villages-sanatoriums de haute altitude" was formed and a suitable site for development was selected at Passy, a sunny sheltered plateau about 4000 feet above sea-level and not many miles distant from the Mont Blanc range. Eight sanatoriums have now been built in this neighbourhood containing in all 1200 beds. A thoracic surgeon from Paris pays regular visits so that operations when required can be carried out without breaking the continuity of sanatorium treatment which is so well organised by Dr. F. Tobé. The bulletin[1] recently produced by the group of Passy doctors, intended as the first of a series, describes the health resort and its amenities, with a number of short clinical papers illustrating problems of treatment. Among these is a paper by Dr. J. Rolland and Dr. A. Maurer on pulmonary complications consecutive to thoracoplasty. Thirty-six post-operative complications occurred in 169 cases and sixteen of these ended fatally. Basal congestion was found to be more frequent after phrenic evulsion, and the authors deprecate routine paralysis of the diaphragm on the affected side. As might be expected, complications were relatively few among patients who had lost their fever and toxæmia during a preliminary period of sanatorium treatment. Those with a large amount of sputum, and in particular those showing a fluid level in a cavity, were especially prone to post-operative pulmonary complications. Full use is being made at Passy of the exceptional facilities for the clinical study of tuberculosis, and further bulletins will be awaited with interest.

REBUILDING PROGRAMME

THOUGH local conditions provide the text for the argument in a stimulating study[1] of the housing question in Manchester Sir Ernest Simon is better qualified than most people to write on housing problems in general, and much of what he says deserves a wider application. Beginning with a glance at the terrible story of laissez-faire in the housing of the lower paid workers, he and his collaborator set out the achievements of the city council in reconditioning, in building new houses, and in town-planning. One of the most important parts of the book is the section, to which Lady Simon contributes, on Wythenshawe, the first complete garden city planned as a satellite by a local authority. All the difficulties, parliamentary as well as local, which have delayed the development of Wythenshawe are described in detail and quite impartially. The conclusion stands out that a big local authority is very well placed to foster the garden city movement, because it can supply both cheap capital for development and houses in large numbers to make the capital remunerative. The absence of these two factors has done much to retard the successful growth of Welwyn and Letchworth. It is perhaps going rather far to say that the garden city movement can only succeed if it is sponsored by our great cities, but it is highly probable in view of the success of the Wythenshawe experiment that this is the line which garden city development will generally follow. The story of Wythenshawe illustrates two conditions which are vital to success in an enterprise of this kind: (1) the mother city must own the land, and (2) it must also be the local authority for the satellite. To state these two conditions is to indicate some of the difficulties to be overcome, but it is to be hoped that even now many progressive local authorities are laying plans to follow the example of Manchester.

In discussing the future Simon and Inman emphasise the need for a long range plan, and give reasons for the view that factors of population, transport, and trade are likely to be more stable and therefore more amenable to plan during the coming than during the past 100 years. The relative merits and costs of cottages and flats are compared, the former being favoured. In conclusion, a time plan is suggested, stretching over a century, of which 50 years are allotted to the building of 20,000 additional houses and to the replacement of the whole of the existing slums in Manchester, and 50 years thereafter to the rebuilding of the business centre. The cost of the first 50 years' programme, including a second satellite garden city, is estimated at £50,000,000, apart from Government subsidies, and in this connexion it is noteworthy that during the fourteen years, ending 1934, the expenditure of the housing department has been on an average £1,000,000 a year, precisely the figure estimated for the future.

The problems of replanning a built-up area are different from and more complex than those of creating a new garden city on an agricultural site. Here also if the slums are to be rebuilt the city council must do it. An incidental result will be the transfer to the municipality of the freehold of most of its area. It is significant of the change of public opinion on housing that these far-reaching proposals should be made.

---

[1] The Rebuilding of Manchester. By Sir E. D. Simon, M.A., chairman of the Manchester Housing Committee, 1912–23, and J. Inman, B.A. London: Longmans Green and Co., Ltd. 1935. Pp. 173. 5s.

TREATMENT OF SYPHILIS DURING PREGNANCY

CONGENITAL syphilis may be an irreparable tragedy for the victim, and the fact that syphilis in the new-born living child is readily amenable to early treatment is no excuse for allowing women to go through a full-term pregnancy after several miscarriages, only to be faced ultimately with a florid syphilitic offspring. In an admirable survey of 2150 pregnancies in coloured women whose Wassermann reaction was positive, carried out over a period of 17 years, J. R. McCord,[1] of Atlanta, Georgia, shows that timely treatment of the mother assures her of a syphilis-free baby in 95 per cent. of cases. What he rightly calls "disastrous pregnancies" can in fact be reduced from 49·4 per cent. in the untreated to 5·4 per cent. in the treated by insistence on a routine Wassermann reaction early in pregnancy, followed by a combined arsenical and mercurial course. Dr. McCord bases his treatment entirely on the prevention of disease in the baby. "We make no effort," he says, "to cure the disease in the mother." But while those in this country who have had similar opportunities will agree with him that it is desirable for pregnant women to have a Wassermann reaction done at least once during pregnancy, preferably early enough to ensure six months' treatment before the birth of the child, they will not agree with McCord's principle that antepartum therapy should be based only on the prevention of the disease in the child, not on its eradication in the mother. His criterion of sufficient treatment designed to this end is 10 injections or more once a week of 0·45 gramme N.A.B. combined with a heavy metal (mercury or bismuth), and he recommends the continuance of the treatment irrespective of its effects on the mother's Wassermann reaction. There is in fact little danger in submitting pregnant women to rigorous antisyphilitic treatment extending over more than twice the period suggested. By this means it would be possible almost to guarantee the birth of a healthy child as far as freedom from syphilis is concerned, and the mother would herself be receiving curative rather than merely palliative treatment.

AN ANGLO-SCANDINAVIAN PILGRIMAGE.—The Viking Society, of which Mr. A. Rugg-Gunn, F.R.C.S., is president for the third successive year, is organising a celebration at Shaftesbury on Oct. 5th in honour of the ninth centenary of Canute the Great. The meeting will be attended by several Scandinavian ambassadors or their representatives, and, it is expected, by the Earl of Shaftesbury, Lord Lieutenant of Dorset. The programme includes an Anglo-Scandinavian religious service in the Abbey ruins, a reception by the Mayor, luncheon, lecture, ramble around the historic city, and tea. The inclusive cost of the pilgrimage is one guinea per head, and any medical man or woman is welcome to join it. Application for tickets should be made to Mr. A. W. Johnston, 30, Goblin's Green, Welwyn Garden City.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXIX.—PROGNOSIS IN JEJUNAL ULCER

JEJUNAL ulcer is used as a comprehensive term to include ulceration occurring in the jejunum, around the margin of the stoma and in the duodenum following gastro-duodenostomy. The prognosis is much the same in all although it has been stated that the purely jejunal ulcer has a slightly greater tendency to perforation while the marginal ulcer is more prone to develop adhesions with secondary involvement of the transverse colon.

A review of the literature does not reveal any reference to the prognosis but results of treatment are given on the medical side by A. F. Hurst and M. J. Stewart (THE LANCET, 1928, ii., 742), and on the surgical side by A. J. Walton (Brit. Jour. Surg., 1934, xxii., 33) and Garnett Wright (Ibid., 1934, xxii., 433). Hurst claims that quite a large proportion of cases can be cured by medical means provided the patient adheres closely to a prescribed régime. His figures are set out in Table I.

TABLE I.—(*Hurst*)

Cases in New Lodge series	35
,, treated medically	25
,, with satisfactory result	13

Walton and Garnett Wright on the other hand regard the results of medical treatment as most unsatisfactory, practically all cases coming to operation sooner or later. They agree that these cases offer some of the biggest and most difficult problems in the realms of surgery and that the results are by no means brilliant. For brevity I have reproduced Garnett Wright's final table of results in Table II., and given A. J. Walton's results in Table III.

TABLE II.—*Results of Operative Treatment* (*Garnett Wright, 456 cases*)

Good	150	Later results unknown		130
Fair	29	Died as result of	operation	91
Symptoms still present	44		disease ..	12

TABLE III.—*Immediate Results of Operative Treatment* (*Walton, 79 cases*)

Cases	79
Operation of partial gastrectomy	61
Deaths	16

In a personal communication Sir James Walton tells me that the later results of partial gastrectomy in his series have not yet been published, so that from his figures one is unable to assess the true value of this particular operation. Tables II. and III. show a high operative mortality, although it must be pointed out that in the last 20 of Walton's series only one death occurred. After deducting the untraced cases, Table II. shows a percentage of 51·8 per cent. as cured, while Table III. gives 57 per cent. as the proportion of partial gastrectomies successful as far as immediate results are concerned. Neither Walton nor Garnett Wright is in favour of small local operations because of the extreme liability to recurrence of ulceration; both recommend the bigger operation, namely, partial gastrectomy, provided the patient's general health is thought good enough to stand the strain.

RUTHIN CASTLE CASES

For the purpose of this paper I have collected and followed up 30 cases of jejunal ulcer admitted to Ruthin Castle. All have been traced up to the present time. The mode of treatment, whether medical or surgical, was decided after full consideration of the clinical and radiological data in each case. Cases showing an uncomplicated ulcer without marked mechanical defects of the stoma or loops (as shown by X rays) were treated by medical measures in the first instance, but if the immediate response was poor or the patient relapsed soon after a complete and thorough course, operation was advised. Of the 30 cases, 14 were treated by medical means alone; a further 8 relapsed after medical treatment and were operated upon. The results in these two groups are shown in Tables IV. and V.

TABLE IV.—*Results of Medical Treatment* (14 *cases*)

Cases cured	9
,, improved	1
Still complaining of symptoms	2
Dead	2

The 9 cases labelled "cured" have remained well for periods ranging from 4 to 10 years. The two deaths were due to sudden large hæmorrhages. In one this occurred twelve months after treatment and the patient had complained of no symptoms whatsoever. In the other intermittent mild indigestion had continued in spite of careful after-care.

TABLE V.—*Operation and Result after Medical Treatment had Failed*

Case.	Operation.	Result.
1.	Gastro-duodenostomy	Good.
2.	,, ,, ...	Patient dead.
3.	,, ,, ...	Poor.
4.	Local operation and then partial gastrectomy	Good.
5.	Do. do. ..	Patient Dead.
6.	Two local operations	Good.
7.	,, ,, ,, ...	Good.
8.	,, ,, ,, ...	Poor.

In this group five cases had to be operated on twice, showing the poor and uncertain results of local operations, which tends to confirm what Walton and Garnett Wright had found in their series.

The remaining 8 out of the 30 were immediately subjected to operation, the clinical and radiological findings being such that medical treatment was contra-indicated. These findings were: (1) gastro-colic fistula; (2) obstruction due to inflammatory thickening around the ulcer; (3) probable involvement of the transverse colon as shown by lower abdominal pain and distension or by radiological signs of adhesions to, and irritation of, the large bowel close to the site of the ulcer; (4) repeated serious hæmorrhage; (5) failure to respond to medical treatment before admission; (6) marked mechanical deformities of stoma or loops as shown by radiological examination.

In this group there were 3 cases of gastrocolic fistula and all died immediately after operation; 2 cases ultimately had 4 operations each, both being finally subjected to partial gastrectomy; one did well and the other died as a result of the operation. Of the remaining 3 cases, one has had two local operations and is now fairly well; the second has had three local operations and is now doing well, while the third had an immediate partial gastrectomy and has remained well for four years.

To sum up—17 cases, that is, rather more than half, have done well and there were 9 deaths in the series. The results of medical treatment compare quite favourably with those of surgery, although it must be remembered that only the unresponsive and complicated cases were submitted to operation. It is clear that chosen cases of jejunal ulcer can be cured by medical means, and this is in agreement with the findings published by Hurst. Also the analysis of our cases goes to confirm Walton's and Wright's contention that local operations prove unsatisfactory and that partial gastrectomy offers the best cure if surgical interference is inevitable, even though the mortality of this operation is high.

The study of this series has brought out certain other factors which may have a bearing on the prognosis. The average age on admission was 46; 9 patients were 40 years old or under, and of these 2 had four operations each and 6 had two operations each; while of the 9 patients who did well medically, 7 were over 55 and there was only 1 under 40. If any conclusion as to the effect of age on prognosis can fairly be drawn from so small a series, it is that jejunal ulcer is more serious and harder to cure in patients under 40 years of age, while those over 55 tend to do well with medical treatment provided there are no complications.

The fractional test-meal findings are also interesting. This test was done on 21 out of the 30 cases. Superacidity was present in 15; normal acidity in 2 and subacidity in 4. Of those with superacidity 8 were treated medically and 7 did well; 7 were treated surgically and 4 did well. Thus superacidity is frequently found in this disease, but this in itself does not seem to affect the ultimate prognosis. However, it confirms the common-sense view that careful dieting and alkalis should be continued indefinitely, bringing this aspect of the disease into line with the accepted principles of treatment in duodenal ulcer. The importance of this after-care has been emphasised repeatedly by the doctors who have written about the patients' present condition, it being frequently stated that the maintenance of a good régime usually means health, while the reverse leads to recurrence of symptoms and chronic ill-health.

Finally temperament, economic position, and mode of living have more than a little influence. The phlegmatic individual whose circumstances of life are such as to be able to avoid much worry is more likely to do well. It is instructive to note that 5 out of the 30 cases occurred in doctors who are prone to irregular hours, hurried meals, scanty holidays, and often an anxious existence.

Complications.—In our series the most dangerous complications were: (1) gastrocolic fistula, 3 patients, all of whom died; (2) perforation into abdominal cavity, 3 patients, 1 died and 2 still have disabling symptoms; (3) repeated severe hæmorrhage, 10 patients, 4 of whom died; (4) obstruction with cyclical vomiting, 2 patients; (5) persistent pain which led to morphia addiction, 3 patients.

CONCLUSIONS

(1) Jejunal ulcer must be regarded as a grave complication of gastroenterostomy.

(2) Patients must be considered individually as to whether the primary treatment should be medical or surgical, and medical treatment should be given a trial in all uncomplicated cases.

(3) Of surgical procedures partial gastrectomy seems to be the most useful.

(4) In all cases after-care plays an important part.

(5) The most serious complications are gastrocolic fistula, perforation, and repeated hæmorrhages.

R. P. Picton Davies, M.D., M.R.C.P.,
Physician, Ruthin Castle, North Wales.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdrs. A. Craig to *Victory* for Haslar Hospital, and J. H. B. Crosbie to *Victory* for R.M. Infirmary, Portsmouth.

Surg. Lt.-Comdrs. E. C. Davis, A. L. McDonnell, and S. G. Weldon to be Surg. Comdrs.

Flight Lts. L. S. Everett to R.A.F. Station, Ismailia, and J. Magner to No. 1 School of Technical Training (Apprentices), Halton.

Flying Offrs. P. A. Cooper to Central Flying School, Upavon; L. E. A. Dearberg and R. C. H. Tripp to Princess Mary's R.A.F. Hospital, Halton.

Fellowship of Medicine and Post-Graduate Medical Association.—The following courses will take place on the undermentioned dates: chest diseases at the Brompton Hospital (Sept. 23rd to 28th, all day); dermatology at St. John's Hospital (Sept. 30th to Oct. 31st, afternoons); proctology at the Gordon Hospital (Sept. 30th to Oct. 5th); cardiology at the National Hospital for Diseases of the Heart (Oct. 7th to 18th, all day); medicine and surgery at the Metropolitan Hospital (Oct. 7th to 19th, all day); anatomy and physiology at the Infants Hospital (Oct. 7th to Nov. 29th, Monday, Wednesday, and Friday evenings). Special concentrated week-end courses will also be given as follows: ophthalmology at the Royal Westminster Ophthalmic Hospital (Sept. 28th and 29th); fevers at the Park Hospital (Oct. 5th and 6th); heart and lung diseases at the Royal Chest Hospital (Oct. 12th and 13th); obstetrics at the City of London Maternity Hospital (Oct. 19th and 20th). There will also be lectures on X ray interpretation at the Medical Society of London, Chandos-street (Sept. 30th to Oct. 4th at 5 P.M.); on endocrinology at the National Temperance Hospital (Tuesdays and Thursdays, Oct. 8th to 24th at 8.30 P.M.); gynæcology at the Medical Society of London (Thursdays, Oct. 10th to Nov. 7th at 4 P.M.). Detailed syllabuses can be obtained from the secretary of the Fellowship, 1, Wimpole-street, London, W. 1. Courses and lectures are open only to members and associates of the Fellowship.

SPECIAL ARTICLES

PLASTER TECHNIQUE IN THE MODERN TREATMENT OF FRACTURES

BY K. H. PRIDIE, M.B. Lond., F.R.C.S. Eng.
SURGICAL REGISTRAR TO THE FRACTURE CLINIC AND ORTHOPÆDIC DEPARTMENT OF THE BRISTOL ROYAL INFIRMARY

THE great advance in traumatic surgery during the last few years has resulted from the adoption of the principles and methods of Dr. Lorenz Böhler, director of the Hospital for Accidents in Vienna. In his book on the treatment of fractures, which is available in translation to English readers,* he emphasises the vital importance to the community of the organised treatment of fractures, which should no longer be left to junior house surgeons to treat. There is probably no branch of surgery where the difference between efficient and inefficient treatment is so marked; for instance, a man with a simple fracture of the leg, instead of being back at work in three months, may be crippled for life with an ununited fracture or a painful leg. The saving of compensation and of lost wages repays the cost of the clinics many times over.

It is the organisation of these special clinics that is so important; first, because it is not economic to apply the method to individual and isolated cases, and secondly, because a great factor in the success of the method is psychological. To see other patients with leg injuries similar to his own walking without pain after a few days has such a good effect on the new patient that he is no longer a mental invalid, and very rarely is the compensation neurotic encountered. Many cases of Pott's fracture and fracture of the tibia can walk home the same day as their injury, and need not stay in bed one day. Many of them are able to carry on their work and women patients are able to look after their housework. But no amount of physiotherapy, electrical treatment, or massage will restore full function to a patient whose fracture has been incompletely reduced. It is waste of time and money for a patient with an unreduced Colles's fracture to receive massage and physiotherapy, for the end-result will only bring discredit to the masseuse.

A childish superstition of reverence surrounds a padded piece of wood. Often a patient is sent up to hospital in a splint whose weight is causing painful displacement of the bone-ends, for example, a back-splint and foot-piece used for a below-knee fracture. In the case of a Pott's fracture, a firm bandage over wool gives far more support than a back-splint and foot-piece where the foot is anchored to the splint and the tibia is free to rotate and cause displacement and pain. Patients in these splints dread being touched, and frequently remove them when the doctor has gone. Böhler has introduced the unpadded cast as a method of fixation after reduction. Plaster-of-Paris is unequalled for the fixation of fractures, but the method of application has to be learnt, and unless the surgeon knows how to apply these casts the results will be poor. After the application of unpadded casts the patients feel comfortable, they sleep at night, and no longer dread being touched.

The removal of splints for massage is wrong; there is risk of displacement of the fractured bone-ends. The only massage the patients need is the massage of function. Massage should not be allowed till the bones are firmly united; then, if the reduction has been satisfactory, and the patient has been using the limb, there will be full range of movement two weeks after removal of the plaster.

It is so essential for the teaching of students to secure a plaster of standard weight, strength, and application, that a bandage of constant composition must be used. Hospital-made bandages vary in different institutions, and even in different wards of the same institution. For these reasons I have adapted my technique to the three-yard Cellona bandage.† Cost and comfort have been the main factors in the evolution of this technique. The cost of the entire treatment is greatly diminished for these reasons:

1. The surgeon's time is only spent on reduction and fixation of the fracture.
2. Using these methods the majority of fractures can be treated as out-patients, hospitalisation being avoided.
3. Patients' visits and travelling expenses are reduced to a minimum.
4. Physiotherapy (a costly form of treatment) is only required in about 5 per cent. of cases, as compared with 100 per cent. using the old methods. The patient by his activity performs his own physiotherapy.
5. The majority of patients are able to follow their own occupation, without consequent loss of wages, and in any case disabilities and invalidism are avoided. Women can perform their household duties without outside help, and children can continue to attend school.

Besides this it is possible with the technique to produce casts of a

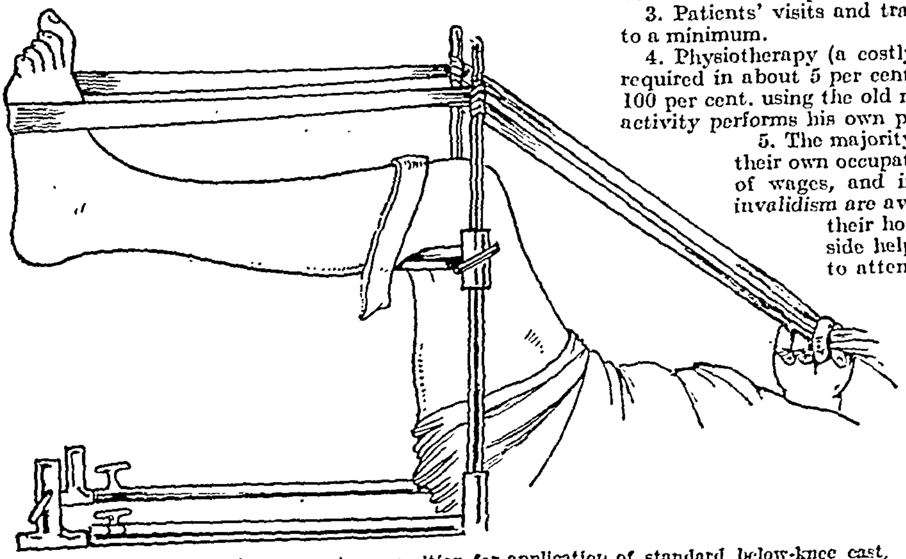

FIG. 1.—Böhler extension apparatus: position for application of standard below-knee cast, in cases not needing skeletal traction for reduction.

---

* The Treatment of Fractures, by Dr. Lorenz Böhler. Fourth English edition. Translated from the German by E. W. Hey Groves, emeritus professor of surgery, University of Bristol. Bristol and London. 1935. (Reviewed in THE LANCET, 1935, i., 992.)

† The Cellona bandage, which is made by the manufacturers of Elastoplast (T. J. Smith and Nephew Ltd., Neptune-street, Hull), contains 90 per cent. by weight of plaster; the setting time may be regulated as desired; and although exceptionally strong, it is the lightest plaster bandage yet produced.

minimum weight, an advantage in ambulatory cases of lower-limb fractures.

First Principles

The three principles of fracture treatment are :

1. To reduce the displaced bone-ends as soon and as accurately as possible.
2. To maintain uninterrupted fixation of these bone-ends until union is firm enough to dispense with external splinting.
3. To use the affected limb as much as possible during the period of fixation.

The period of disability following any fracture is determined by the accuracy of reduction. The blood-vessels and lymphatics at the site of a fracture are often kinked or pressed on by displaced bone-fragments, causing œdema ; this indirectly leads to stiffness, muscle adhesions, and limited movement. Following a fracture, there may be three displacements :

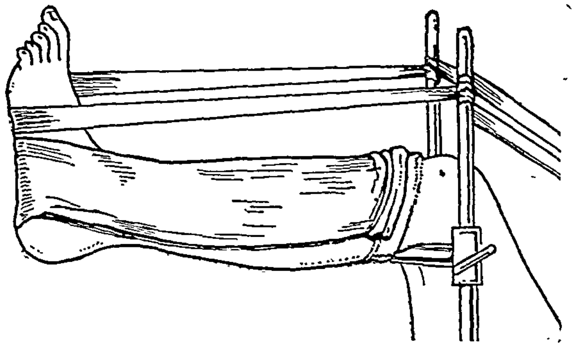

FIG. 2.—U-shaped slab applied to the limb ; the excess is turned back so that it does not project beyond the felt.

1. *Shortening.*—This can be easily corrected if the reduction is performed during the first few hours following the accident, but, if muscle-adaptive shortening has taken place, this deformity is extremely difficult to overcome. There is no excuse for shortening to occur in a fracture case, unless there has been actual loss of bony substance.
2. *Lateral displacement.*—It is frequently not possible to replace the bones exactly into their previous anatomical position, but provided there is no angulation, this lateral displacement may cause no disability, although it may give rise to swelling and prolong the time of healing.
3. *Angulation.*—Perfect apposition of bone fragments is of no use if angulation is still present. Angulated bones tend to bend and frequently cause arthritis in the joints above and below the fracture, due to the mal-direction of weight-force.

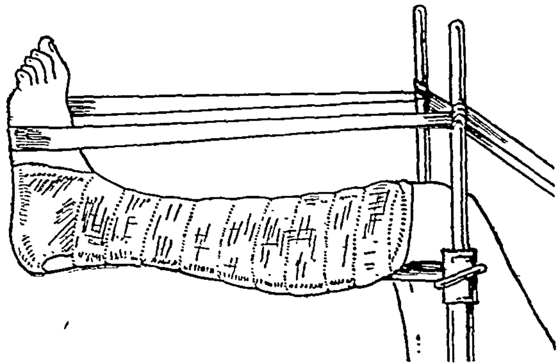

FIG. 3.—U-shaped slab fixed to limb by means of a wet gauze bandage.

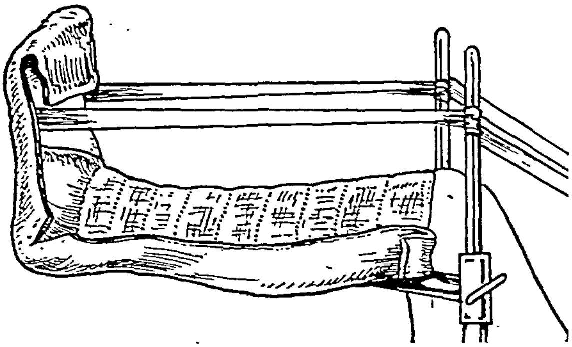

FIG. 4.—Back-slab applied.

If the function of the neighbouring joint is not to be severely handicapped, great care must be taken in the reduction of fractures of bones near joint surfaces, for example, fractures around the knee-joint, Pott's fractures, fractured surgical neck of humerus, supracondylar fractures, Colles's fractures, fractures of radius and ulna. The radius rotates around the ulna, and any marked angulation of the radius from its normal shape will block the movements of pronation and supination.

Stiffness of joints following an injury is chiefly due to muscle adhesions, and these do not form if the limbs are used during the whole period of disability. The following written instructions should be given to each patient at the first visit :

1. For the next 12 hours, when not actively moving the injured limb, it must be kept elevated and not allowed to hang down and thereby encourage swelling.
2. During the night time the injured part must be kept elevated above the rest of the body. For instance, the forearm must be placed on a pillow across the chest and the leg raised on a pillow resting on a box.
3. During the day the fingers, in the case of a fractured arm, must be kept moving constantly. An injured leg is to be used as much as possible and the patient should be able to walk up to one mile within the first week, increasing to greater distances in subsequent weeks. No crutches should be used, only sticks, which should be soon discarded. No slings to be used, but the hand, when not in use, must be kept elevated by making the fingers grip the opposite coat lapel.
4. Should the plaster become tight the patient must immediately report to the doctor, so that the plaster may be split. (In every cast a portion equal to at least a quarter of the circumference of the limb is extremely thin, and can be cut with ease.)

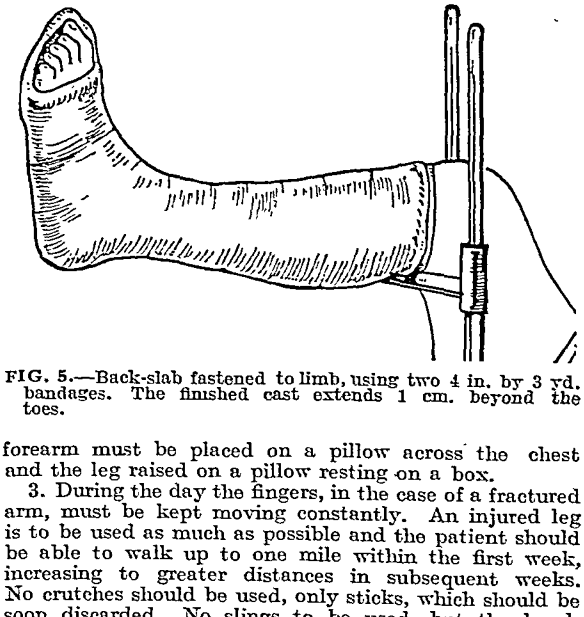

FIG. 5.—Back-slab fastened to limb, using two 4 in. by 3 yd. bandages. The finished cast extends 1 cm. beyond the toes.

Indications of too tight a cast are swelling, blueness, or numbness of the extremities, not relieved by elevating the limb, and inability to move the toes or fingers. The patients must be seen daily until there is no further fear of swelling. If a limb is *greatly swollen* when first seen, it is not completely surrounded by a cast until the following day.

Possible causes of failure in using this technique are:

1. The *fracture* may not have been reduced. Plaster casts must not be put on unreduced fractures.
2. The cast may fit badly. Complete plasters must not be applied to arm fractures on the first day, but only after reduction has been verified by X ray and the swelling has diminished. If a limb *is grossly swollen* at the time the fracture is reduced, the swelling must be massaged with the limb elevated before the cast is made. If this precaution is not taken the cast will become loose when the swelling diminishes. If the swelling cannot be reduced in this manner, a temporary, non-completed cast must first be used, until the swelling has been reduced.
3. Inadequate use of the injured part, leading *to stiffness of joints.*

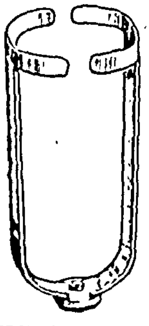

FIG. 6.—Böhler iron. Bristol pattern. (Medical Supply Association.)

Technique

1. The limb should be cleaned with ether soap. Strong antiseptics should not be used, as these kill the skin. *Dead skin under plasters forms* an excellent nidus for bacteria.

2. If the limb is obviously broken, and the fracture site is easily seen, the leg should be rendered painless by the administration of local anæsthesia into the hæmatoma between the fragments. The taking of true antero-posterior and lateral view radiograms is then no longer a painful procedure. Often the radiologist is unable to secure a true lateral view of a fracture because of the great pain entailed by moving the patient; local anæsthesia here relieves much suffering.

3. The limb should be reduced as soon as possible following the fracture. If the case is left, swelling and œdema will occur, and even skin blistering. If the reduction can be carried out within a few hours of the accident, no swelling will occur.

4. If the fracture for some reason cannot be reduced *immediately, the following* procedure is recommended:

(*a*) Any gross deformity can be corrected by hand. This relieves kinking of blood-vessels and tends to prevent swelling.

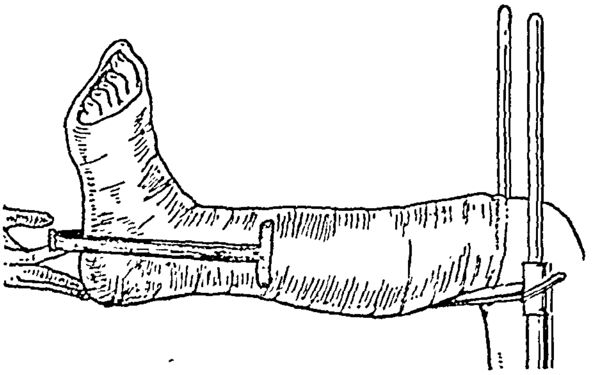

FIG. 7.—Application of Böhler iron.

(*b*) A firm bandage—e.g., Elastocrêpe—should be applied over wool, from the extremity of the limb to above the fracture site. This supports the tissues and prevents swelling.

(*c*) An adequate back-splint should be applied. A padded Cramer wire splint is light and efficient. A back-splint and foot-piece from toes to knee will do nothing but harm to a fracture *of the middle* or upper third of the tibia.

(*d*) The injured part should be kept elevated above the rest of the body, until adequate reduction can be performed and the fixation cast applied.

If the patient is to walk the same day as his fracture, which is the ideal to be aimed at, the following conditions are essential:

1. The reduction must be performed *before the limb* has swollen.
2. If the limb has swollen, this must be reduced by elevation, massage, and anodal galvanism, applied by means of pads. A complete plaster cast must never be placed *on a swollen limb.*
3. The limb must not be shaved before applying the plaster cast.
4. The *patient must be seen by the doctor the next* day.
5. The printed instructions already described must be given to the patient.

PREPARATION OF BANDAGES FOR USE

1. The total number of bandages required *for any* particular cast should be determined, removed from their containers and placed in an accessible position facing the operator.

2. All slabs should be made on an armoured glass plate, *the most suitable dimensions* for which are *40 × 12 ×*

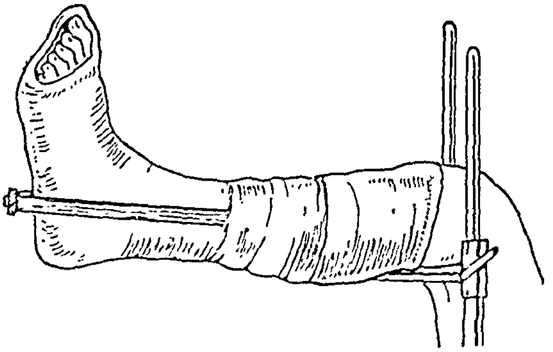

FIG. 8.—Bandage 4 in. wide holding top of iron.

½ *in.* The glass plate should be placed across the sink and tilted laterally so that any excess of water will run off; otherwise slabs will be too moist.

3. A glass rod, about 11 × ⅜ in., is inserted through the cardboard core. The complete bandage is immersed for *three seconds* in a bowl of tepid water. Both hands should be employed to remove the bandage and squeeze out excess moisture.

4. The loose end of the bandage is held on the glass plate and the bandage unwound by means of the glass rod to the requisite *length for the* slab. A second thickness is secured by unrolling the bandage on to the first layer, and the operation is repeated until the necessary *number of layers* are obtained. As the bandage is unwound the layers should be smoothed out by hand to remove all air cavities.

5. The finished slab, now ready for application, is slid off the glass plate on its long axis to avoid drawing the layers apart.

The Below-Knee Cast

1. When swelling has been reduced, the leg is placed as shown in Fig. 1. The bandage, which is held by the patient, is used to keep the foot dorsiflexed.

2. A strip of adhesive felt, 1¼ in. wide by ⅛ in. thick, is placed obliquely as shown in Fig. 1; it must be higher *anteriorly* than posteriorly, to allow full range of flexion later.

3. A slab 40 in. long is made with two *4 in.* by 3 yd. bandages. *This is applied* as a stirrup, from the adhesive felt on the inner side, round the heel, to the adhesive felt on the outer side (Fig. 2). The

slab is rubbed on to the limb and all air bubbles displaced. *This is essential during the whole process of application.*

4. This slab is held in position by applying a wet muslin bandage from above downwards to just above the ankle. This bandage should be of thin gauze 1½ in. wide with trimmed edges, and should be rolled on loosely (Fig. 3).

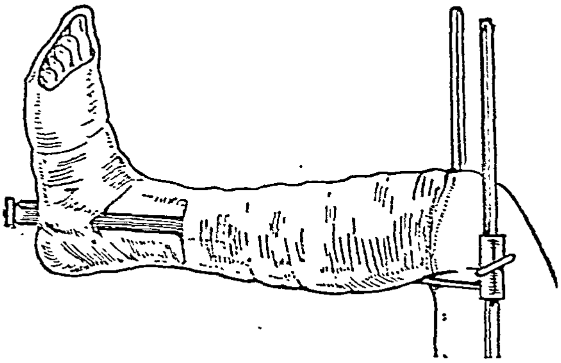

FIG. 9.—Bandage 4 in. wide holding bottom of iron.

5. A back-slab 40 in. long is now made from two 6 in. by 3 yd. bandages. This is applied working from above downwards, along the calf, over the sole of the foot, and the excess dropped temporarily over the toes. The operator now makes a cut 1 in. long on each side of the ankle-joint, so that the bandage will mould snugly round the ankle and heel (Fig. 4).

6. A 4 in. by 3 yd. bandage is applied in a circular manner from above downwards, a small fold being made in each turn (the crease of the fold coming over the back-slab and *not over the bare area of the tibia*); this allows for the slight contraction of the bandage in setting. The bandage will reach to the ankle-joint.

7. The portion of the back-slab which was thrown over the dorsum of the foot is now doubled back over the plantar surface, making a double support under the toes. This plaster should extend 1 cm. beyond the toes.

8. A second 4 in. by 3 yd. bandage is applied in a circular manner, extending from the ankle to the toe cleft (Fig. 5).

9. A slab 20 in. long is made from half a 4 in. by 3 yd. bandage. This is put round the top of the plaster tightly and held on by using the rest of the bandage. This completes the top of the plaster and makes it firm to stand the weight of the leg.

10. A modified Böhler iron (Bristol pattern, as shown in Fig. 6) is attached to the cast, in the axis of the tibia, and extending two fingers-breadth below the heel. The clearance of the iron must depend on the amount of dorsiflexion able to be produced. If the foot has been fixed in a position of dorsiflexion just over a right angle, two fingers-breadth is the ideal clearance. There must be sufficient height of iron to allow the plaster under the toes to clear the ground.

11. Half a 4 in. by 3 yd. bandage, applied tightly round the cast, holds the top of the iron (Fig. 7). The other half is used to lash the iron to the heel (Fig. 8). Heavy patients will require one whole bandage (4 in. by 3 yd.) in each situation.

Ten minutes after the application of this cast the patient may walk on the iron. He must be given the following instructions:

1. You must walk with a straight knee, and on no account go over on to the toe-support of the plaster, or this will wear out and crack.
2. When not walking you must keep the leg elevated.
3. Read the printed plaster instructions about visiting the doctor.

This is a standard cast for all ankle fractures except Pott's of the third degree. The indications for its use are:

1. Fractures of the metatarsal bones.
2. Fractures and dislocations of the mid-tarsal bones after reduction.
3. Fractures of the os calcis (with certain modifications).
4. Severely torn ligaments of ankle-joint.
5. First and second degree Pott's fractures.
6. Cases which have had operative correction for foot deformities such as Steindler's operation and tendon transplants, subastragaloid arthrodesis. A padded cast is first used for a week.

Number of bandages required ..	6 4 in. × 3 yd. 2 6 in. × 3 yd.
Weight of cast plus iron	2½ lb.

This cast is the standard basis of the long and the short casts, the long casts always being made in two sections, the first section being this standard below-knee cast.

The Mid-Thigh Cast

This is made in two sections, first to the knee as described above, and then to the mid-thigh, with the knee in extension, as follows:

1. A piece of adhesive felt 1½ in. wide and $\frac{3}{16}$ in. thick is placed round the mid-thigh.
2. A slab 30 in. long is made from two 6 in. by 3 yd. bandages. This is applied to the front of the thigh with a small fold back at the upper end from the adhesive felt above, to 8 in. down the tibia. The surplus is cut off and applied over the junction of the two plasters.
3. A back-slab is made from two 6 in. by 3 yd. bandages. This is similarly applied to the back of the thigh.
4. These slabs are fixed to the limb by two 4 in. by 3 yd. bandages applied in a circular manner.
5. A 4 in. by 3 yd. bandage is made into a slab and applied to go round and strengthen the top.
6. When the patient has large thighs it is advisable to apply, in addition, two lateral slabs made from 4 in. or 6 in. bandages, according to the size of the limb.

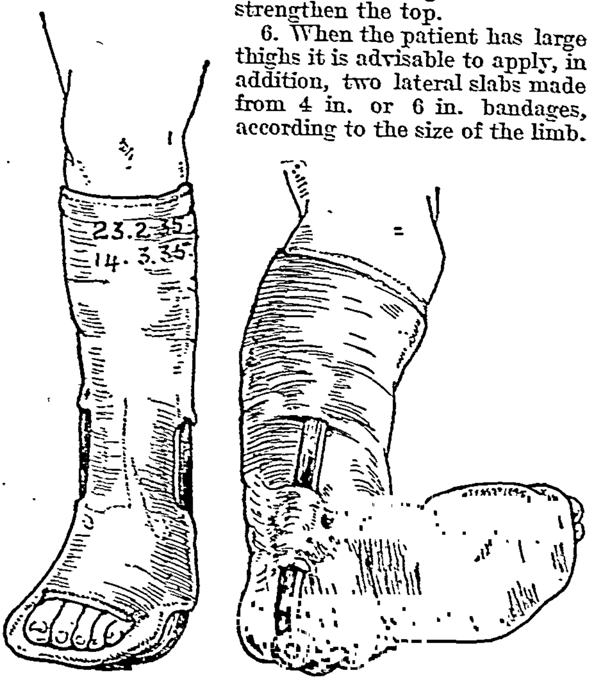

FIG. 10.—Standard below-knee cast completed. Note the date of reduction and the date of removal of cast.

Indications for the mid-thigh cast are:

1. Third degree Pott's fracture.
2. Pott's fracture in corpulent women, where the below-knee cast does not produce sufficient immobilisation to enable them to walk without pain.
3. Fractures of lower third of the tibia.

The Full-Length Walking Cast

This extends from the toes to the tuber ischii and is unpadded except for the top, which is constructed similarly to the top of a walking calliper. This cast is made in two parts. First, the standard below-knee cast is applied with the knee in flexion. The knee is then straightened and the cast continued up to the tuber ischii. The padded ring is made as follows:

A 4 in. by 2 yd. domette bandage is sewn round a ¾ in. roll of grey hospital felt, the felt being cut to the exact length of the circumference of the limb round the level of the tuber ischii.

The padding, which is now in a roll form in the middle of the bandage, is put round the top of the thigh so that it lies in the gluteal fold. It is knotted once over the great trochanter and then carried over the opposite shoulder where it is again knotted.

The cast is made as described below, and during the whole process of application the plaster is being constantly rubbed by the operator's hand to remove air bubbles.

1. Anterior slab, 40 in. long, consisting of two 8 in. by 3 yd. bandages, is applied from the ring at the top to 8 in. down the tibia over the lower cast. The surplus is cut off and put over the junction of the two casts, as before.
2. A similar back-slab is applied.

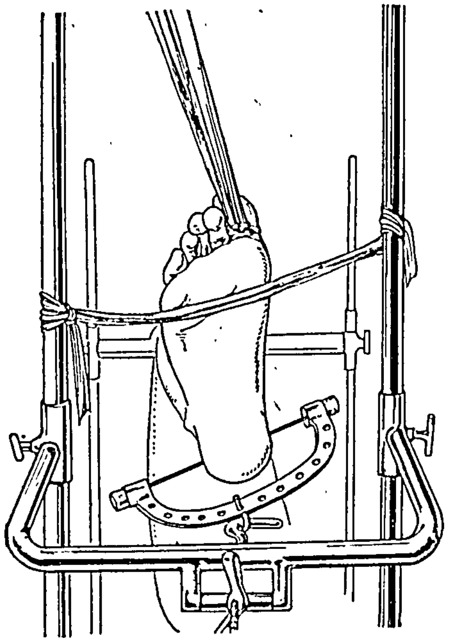

FIG. 11.—Traction with a Kirschner stirrup for difficult fractures.

3. Two lateral slabs are made, each from two 4 in. or 6 in. by 3 yd. bandages, according to the circumference of the thigh.
4. Two 6 in. bandages applied spirally now connect these four slabs together.
5. The top of the cast is now completed by a slab made from a 4 in. by 3 yd. bandage. Before this is applied the ends of the domette bandage are cut off 2 in. from the knot over the great trochanter, and these ends are turned down and incorporated in the plaster.
6. When the cast is dry the top is lacquered to preserve the surface, and enable the cast to be washed when soiled with excretions.

The indications for this cast are: (1) comminuted fractures of lower third of tibia; (2) fractures of mid and upper third of tibia.

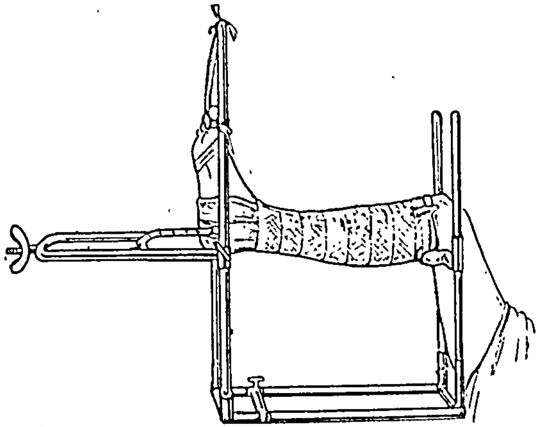

FIG. 12.—A spring balance to prevent overpulling.

Technique in the Swollen Limb

Often the surgeon first sees the case a day or two after the fracture, when the bones have been displaced, there has been a large effusion of blood, and the limb is swollen and œdematous; skin blisters may also be present. Blisters are only seen where the fracture has not been reduced and where a back-splint and foot-piece have been used. In over 800 cases treated by the skin-tight technique, blisters were never seen when the fracture case was reduced within six hours of the accident.

The first treatment should be to clean the skin with ether soap. The leg should never be shaved. If the leg is very flail it should be put straight manually and a firm bandage over wool applied. A padded Cramer wire back-splint is then applied, and the leg kept elevated above the rest of the body till reduction can be performed.

Swelling can be reduced by (1) anodal galvanism by bath or pads; (2) massage in elevation; (3) application of Bier's bandage from below upwards. If the limb at the time of reduction is very swollen a walking plaster must not be applied, because the plaster will rapidly become loose and cease to immobilise the fragments; the patient will then complain of severe pain and will not use the limb.

If the limb is very swollen it is impossible to tell when the bones have been accurately reduced; even if they have been adequately reduced they will become displaced again after the swelling has disappeared, owing to the looseness of the plaster. In such a case a 2/3 plaster is applied, which is kept as light as possible, and removed after the swelling has subsided, in from seven to ten days.

The 2/3 plaster is applied in a similar manner to the standard casts, the only difference being that the circular turns are not used. For instance, in the standard below-knee cast the stirrup-slab is first applied, then the back-slab, and the plaster completed with a wet gauze bandage from the knee to the toe cleft. If the fracture is situated in the lower third the plaster is taken up above the knee—that portion above the knee need not be of the 2/3 variety but can be completed. Swelling is never severe above the first joint above a fracture.

After the cast has set the patient is put to bed and the leg kept elevated for from seven to ten days. The best splint is Braun's which keeps the leg sufficiently elevated, and the foot of the bed is put on blocks. After seven to ten days this cast is removed and a walking cast applied.

In difficult fractures which need skeletal traction for reduction the leg is placed in the Böhler apparatus after a Kirschner wire has been introduced through the heel (Fig. 11). Screw-traction is applied from the Kirschner stirrup to the tension screw. A spring balance is placed as shown in Fig. 12, to prevent over-pulling. The foot is kept in the correct position thus :

1. The pull is exerted on the outer side of the stirrup to invert the heel.
2. The third toe is slung from the cross-frame.

After the reduction has been performed the limb is supported as shown in Fig. 12, and the standard below-knee cast is applied. Slots are cut in the stirrup and back-slabs, to make room for the Kirschner wire. When the plaster is completed the wire is immediately removed.

Ankle Fractures

1st and 2nd degree ..	Cast is of below-knee type.
3rd degree. Pott's ..	Cast is to mid-thigh.
Fracture of post-articular surface of tibia ..	
Lower third tibia ..	
Mid and upper third tibia	Cast is to tuber ischii.

If for any reason it is undesirable to apply the cast above the knee, a mid-tibial fracture may be adequately immobilised by the introduction of a Kirschner wire through the upper part of the crest of the tibia 2 in. below the knee-joint. The wire strainer and wire must be incorporated in the plaster.

(To be concluded)

MENTAL CARE IN 1934

BOARD OF CONTROL REPORT

IN part I. of its report (H.M. Stat. Office, 1*s.* 6*d.*) for the year 1934, the Board of Control (Lunacy and Mental Deficiency) sound a warning that the incidence of mental disorder is increasing at a greater rate than the provision of accommodation. Minor changes provided 1177 new beds ; the total number of patients increased by 2125 and the number of patients in excess of the authorised bed space on the first day of this year was nearly 2000. This, the Board state, would not in itself be a serious shortage but for the slowing-down of new building. Only one new hospital—for Southend and East Ham—is actually being built and, though several others are in contemplation, they are not likely to be ready for four or five years. The shortage of accommodation may become much more serious, say the Board, before it can be appreciably relieved by new construction. The increase in the total number of patients, however, does not give definite evidence that the incidence of mental disorder is increasing, certainly not to an extent which would justify some of the alarmist statements in the lay press.

Satisfactory progress is reported in the administration of the Mental Treatment Act. The number of out-patient centres established in connexion with public mental hospitals is now 134. The Board single out the admirable work of the Hertfordshire Mental Hospital at Hill End, which in addition to many other beneficent activities has established the St. Albans Nerve Clinic (the old-world name was chosen in deference to public taste) where part-time psychotherapists, with the help of trained social workers, assist in providing a form of treatment for which the permanent medical staff often cannot afford the necessary time. This clinic is a splendid example of organisation on a team-work basis.

The number of voluntary admissions to public mental hospitals increased by 1117 and is now over 4000. Admissions under certificate have decreased by 513. The Board note, however, with some uneasiness that a number of mentally defective children of relatively low grade have been admitted as voluntary patients. It is open to doubt, they remark, whether such cases can legally be dealt with under the Act, and they find it difficult to appreciate the grounds on which medical practitioners have given necessary recommendations. They regard this as an abuse of the Act, calculated to bring voluntary treatment into disrepute, and may decide to order the discharge of such defectives as unfit to remain as voluntary patients. The number of temporary admissions increases slowly, but improvement has been noticeable. Many rate-aided patients continue to be certified although a little more time and trouble would give them the benefit of temporary treatment ; the Board have issued a circular for the guidance of relieving officers and hope that it will lessen the difficulties of this complicated section of the Act.

FALSE ECONOMY

The Board learn with regret that one of the largest authorities in the country has decided to reduce the number of medical staff in some of its hospitals. This step, they declare, is all the more unfortunate because the existing medical staff in most public mental hospitals is inadequate if patients are to receive proper individual attention. They cannot believe that the relatively small saving which can be made by reducing a medical officer here and there can be anything but wasteful in the long run. To expand buildings and to diminish staff is, they say, never economical. They also deplore the gradual diminution in the number of whole-time chaplains in mental hospitals. Visiting committees, they say, tend more and more to arrange with the nearest incumbent to undertake the necessary services in return for a stipend which barely represents the cost of an additional curate. The work is therefore done in a more or less perfunctory way by an already busy *incumbent*, or else farmed out to an extra curate. They suggest that, although the visiting committee are primarily responsible, yet it is within the competence of the bishop, whose licence is required for the appointment of a chaplain, to consider whether the conditions attaching to the appointment promise that the duties will be adequately discharged. A chaplain who can spend time in the wards and has the tact and sympathy which call for the confidence of patients does work of therapeutic as well as spiritual value. There is an abundant outlet for the energies of a keen chaplain in educational and recreational work. The Board plead that mental hospital appointments should entitle the holder to relief and transfer at the end of a reasonable time, and that good work should receive more recognition in the selection of men for preferment.

The value of occupational therapy is emphasised, and the Board urge the appointment of whole-time organisers. They do not consider that nurses who learn a craft need necessarily receive extra pay ;

craft-teaching adds to the interest of the work and makes the patients easier to handle, and a specially gifted nurse may secure a post as technician or craft-worker, or may undergo training and qualify as an occupational therapist. To give extra pay seems to the Board to approach the matter from a wrong angle and to invest with a special character what should be a matter of routine. The Board also points out the value of recreations and ward gardens, and of hairdressing and dress facilities for restoring the self-respect of women patients.

RESEARCH

The Board received communications from over fifty institutions reporting progress made in various lines of research. Dr. T. C. Graves, of Birmingham, reports that macroscopic evidence of chronic infection of the nasal sinuses was found in 51 out of 81 post-mortem examinations. The amelioration of mental disorder which follows treatment of bodily disease has, he says, been apparent to all who have been in close touch with the patients. He lays stress on the importance of examining sphenoidal sinuses, and again emphasises that until sepsis of the ear, nose, or pharynx has been treated, real progress towards mental and physical recovery is not made. At Warwick it was discovered that operative procedure did not benefit schizophrenia and manic depressive states but benefited certain confusional states. The visiting dental surgeon at St. Andrew's, Northampton, is not satisfied that dental infection is related to the psychoses except in a few cases. Stereoscopic radiography has been carried out on all admissions but no case of sinus infection was detected. Cardiff continues to test all recent admissions for tuberculosis, and Wadsley (Sheffield) finds that the examination of fæces for the tubercle bacillus is invaluable. Of 41 patients with positive results in the fæces the sputum was positive in 9, negative in 8, and in 24 not obtained or unobtainable. At Long Grove no definite difference was found between cases of dementia præcox and controls in respect to tuberculin, and at Norfolk 25 cases of dementia præcox showed negative blood and cerebro-spinal fluid. At Bristol the routine inoculation for dysentery has been continued and the result has again been most gratifying.

At Storthes Hall the Meinicke clarification reaction was found to agree with the Wassermann in nearly 99 per cent. of 229 admissions, and at Long Grove, where four thousand sera have been examined, agreement has been shown with the Wassermann in all types of cases. As the Meinicke test is much more easily performed, this confirmation of its value is most important. At Winwick the presumptive Kahn test proved in a large series of cases to be practically as good an exclusion test with serum as the micro-Meinicke, but St. Albans considers that the Kahn test is not sufficiently reliable to substitute for the Wassermann. At East Sussex the Kahn flocculation is used concurrently with the Wassermann, and close agreement is found; it is considered that the concordance of these tests is of much greater value than one alone. The Wassermann test, according to the Royal Eastern Counties Institution at Colchester, is often unreliable as a test for congenital syphilis, and cases are being re-examined by the presumptive Kahn test.

Dr. Shaw, of Stafford County, makes an interesting report of the state of the kidney in psychotic patients. He has rarely, he says, found a really healthy kidney at autopsy. Of 242 direct admissions in the year, albumin was present in 45 per cent. and more or less persistently in 70 per cent. of these. Mental hospital patients show "almost constant fatty and exhausted livers," which may furnish evidence of strain and failure in detoxication, with resulting effects upon other tissues. At Barnwood House recurrent attacks of excitement, ascribed to sympathetic stimulation, in a schizophrenic patient have been aborted by acetylcholine.

The Exminster Hospital, Devon, reports good results from the paretic patients it has treated by induced malaria. Out of a total of 79 cases, 32 have been discharged and only four have returned to hospital. Fifteen have continued to improve mentally and 12 have reported good physical health. The mental condition of five was stationary and in two was deteriorating. Ten were in regular employment. In all, 54 are alive, but before malarial treatment was introduced no general paralytic survived longer than three years from admission. Dorset reports a remission-rate of 30 to 35 per cent. from tryparsamide and pyrifer, but the Board considers that malaria still holds the field.

Prolonged narcosis is being investigated by several institutions. Cardiff employed somnifaine in most of 107 mixed cases of mental disorder, eliminating toxic symptoms by glucose and insulin. In schizophrenia the best results were obtained in depressed cases, the least satisfactory in catatonic stupor. In manic-depressive cases 37·7 per cent. are said to have recovered as a direct result of the treatment. Dorset, however, did not obtain satisfactory results, and considers the procedure too dangerous for routine use. This hospital has found that manganese chloride intravenously seems to mitigate catatonic symptoms.

Cardiff contributes a long and interesting report on biochemical investigations.

Mental Deficiency

Steady progress is reported by the Board on the mental deficiency side, and during the year 2026 additional beds were provided in certified institutions. Several big schemes are well under way, including Botley's Park. Considering that the Board have during the last four years put no pressure on local authorities, it is remarkable that the rate of progress has been so well maintained. Comparatively few counties have not made at least a beginning with the provision of beds. The transfer of public assistance institutions to the county and county borough councils has materially contributed to the growing realisation of the cost of neglecting mental defect. The review of accommodation necessitated by the Local Government Act, 1929, brought home to local authorities the extent to which the existing poor-law expenditure was traceable to defectives, and showed that to deal with mental defect through the machinery of the poor law was neither efficient nor economical. The position in Wales, particularly North Wales, is, however, still far from satisfactory, and except in Glamorgan there is little prospect of improvement. In the more thinly populated counties in England and Wales alike the position cannot be expected to improve until agriculture is stable and prosperous.

The Board express uneasiness over the notification of defective children by local education authorities. The local mental deficiency authority, they point out, has no power to deal with children between the ages of 7 to 16 unless they have been notified by the local education authority. This authority can only notify ineducable children and feeble-minded children who are leaving special schools or classes, except where a child could not be taught in a special school without detriment to other children, or the Board of Education certify that there are special circumstances. Special schools have not developed as was anticipated in 1913. Thay are recognised as being impracticable in rural areas and small towns, and even in the larger towns there is sometimes a tendency to merge the feeble-minded and the educational defective with the backward children for educational purposes without certification. This change of policy is in accordance with the recommendations of the Wood Committee, and the Board do not criticise it. Nevertheless, they point out, it clearly restricts in the most unfortunate way the power of local education authorities to notify mentally defective children. The result is that large numbers of defective children who have been retained in ordinary elementary schools cannot be notified when they leave at the ordinary leaving-age, although their defectiveness is well known to their teachers and to the school medical officers. The local mental deficiency authority can do nothing till these children reach the age of sixteen, and then only if they are "subject to be dealt with" under one of the other provisions of the Act. Feeble-minded children are left at a most critical period in their lives without the supervision and control which Parliament intended to give them. Even at the age of sixteen the local mental deficiency authority can do nothing with them unless they are neglected or break the law. Some will find their way into institutions after the opportunity for continuous care and training has been lost, and many will have hardened into delinquent ways. A number who with proper supervision ought not to need institutional care will have got into trouble for want of a helping hand, and some will have so deteriorated that they can no longer be left at large.

The smaller number of notifications from local education authorities may, the Board consider, partly be due to a failure to realise the need of adult defectives for community care, and partly to a lack of provision for care and training outside institutions. Some education authorities are reluctant to take a step which stamps the notified child as being in a class apart. The Board condemn this attitude as wrong, declaring that there is no sharp line dividing the feeble-minded from the dull and backward. The more complicated the social fabric, they say, the greater the need of the defective to have a space found in it for him. Segregation, except for purposes of training, should be a last resort. There is all the difference between a defective left to fend for himself, unprotected and with his weaknesses unrecognised, and one who is given special training, protection, and control. The local authority has the double responsibility of seeing that every defective has proper training and occupation, and of showing the public how to protect mental defectives as they would the cripples and the blind. The expenditure is worth while economically and socially.

CHESHIRE HOSPITALS.—The local authorities in Cheshire have under consideration plans for the provision of adequate hospital accommodation for infectious cases, other than small-pox. Under this scheme a total of 448 beds will be available for a population of 672,781. At present more than half of the 50 county districts have agreements with outside authorities for isolation hospital service and have no control over the hospitals used, and under the new proposals the number of available beds would be increased by 77. It is estimated that the cost will be about £54,900.

MEDICINE AND THE LAW

Alleged Masquerading under Doctor's Name

PROCEEDINGS were instituted at Birmingham earlier in the present month against a man named Ernest Peace Freeman who was alleged to have adopted the name of Dr. Louis Rabinov, a registered medical practitioner residing in Melbourne, Australia. The prosecution stated that Freeman came to Birmingham last year and purchased the practice of Dr. Alexander at Hall Green. He sold it last April to a practitioner from Westcliff-on-Sea for £660. The purchaser afterwards discovered that drugs and fittings had not been paid for. Mr. M. P. Pugh, who prosecuted, said that it had been ascertained that the real Dr. Rabinov was practising in Australia and that Freeman was an impostor who masqueraded under Dr. Rabinov's name. There would, he said, be further charges against Freeman of obtaining £13 worth of drugs and fittings and of obtaining money from the purchaser of the practice and from other persons by the false use of a registered medical practitioner's name. Mr. Pugh added that there had been complaint from the Selly Oak Hospital, Birmingham, that Freeman had been attending lectures in obstetrics at the Dudley-road Hospital and had been examining women. On behalf of the accused it was denied that he had ever been to the Dudley-road Hospital though he seems to have admitted, since his arrest, that his name was not Rabinov, and that he was not a doctor. He was really the owner of the Royal Marine Hotel, Cowes. A police officer told the bench that the real Dr. Rabinov had written a letter which led to investigations. Freeman was remanded on bail till Sept. 26th.

Sequel to Sydney "Shark Arm Case"

We noted previously (THE LANCET, July 6th, p. 40) the quashing of an inquest in Australia on the arm of a missing man believed to have been murdered; the arm had been disgorged by a shark and, though the only part of the corpse to be found, was identified by tattoo marks. The deceased was a boatman who disappeared in April. Soon afterwards a shark, captured in the sea off Sydney and kept alive for a few days in a public aquarium, disgorged the limb. On the day before the inquest proceedings were opened a boatbuilder named Holmes was murdered by unknown men. He had previously made a statement apparently incriminating a third man named Brady as the possible murderer of James Smith. The judge ruled that Holmes's alleged statement was inadmissible against Brady upon the charge of murder. Brady was acquitted. The case is therefore not to be added to the exceptional group of trials where a man has been found guilty of murder in the absence of the corpse.

PARIS

(FROM OUR OWN CORRESPONDENT)

TETANUS IMMUNISATION

LAST week (p. 625) you mentioned the steps now taken to prevent tetanus in the French army. The report of the commission appointed to study the matter is now to hand. The members of the commission, whose president was Dr. Fredet, included Dr. Pierre Duval, Dr. Gosset, Dr. Rouvillois, and Dr. Louis Bazy, who is surgeon to the Saint-

Louis Hospital. Their report to the Société Nationale de Chirurgie is a strong plea for wholesale, systematic, active immunisation with the Pasteur Institute's anatoxin in the place of random passive immunisation with serum, 650,000 ampoules of which were issued by the Pasteur Institute in 1934. To stress the comparative futility of serum treatment, the Commission note that in more than 70 per cent. of the cases of tetanus observed the infection was carried through some trifling injury such as a pinprick or a superficial scratch, and in more than 6 per cent. the site of entry of the germ was not demonstrable. Tetanus serum is apt to be given too late, but whatever may be decided about the routine use of a vaccine, serum will still have a limited field of action, notably in those cases in which the subject of severe infected injuries has not already been vaccinated against tetanus, and is in need of passive immunisation at once. In such cases the Commission recommend a subcutaneous injection of tetanus anatoxin in the scapular region followed about a quarter of an hour later by a subcutaneous injection of serum in the abdomen or thigh; much importance is attached to these two injections being in different parts of the body. The Commission are in favour of combining tetanus vaccination with the typhoid and paratyphoid vaccination already compulsory in the army. For children, tetanus and diphtheria vaccination could be combined. The Commission are in favour of repeating such vaccination every year or two, in spite of the fact that, according to Ramon and Zoeller, the immunity conferred by tetanus vaccination is still demonstrable five years later.

A SANATORIUM FOR FRENCH STUDENTS

Some ten years ago the late Prof. Léon Bernard declared that French tuberculous students should have a sanatorium of their own. This suggestion bore fruit when a sanatorium, differing in many respects from the typical private or public institution, was built at St. Hilaire-du-Touvet, overlooking a wide expanse of characteristic French scenery. Though this sanatorium began to receive patients two years ago, it was not till this summer that it was officially opened by M. Herriot. On this occasion Dr. Rist drew attention to the revolutionary changes which have come over the régime prescribed for the tuberculous since the days, still in the memory of the present generation, when the physician in charge ambled round from one patient to another, preaching the gospel of the simple life and keeping up his patients' morale. The part he played was so easy that he could manage some 150 patients unaided. In the sanatorium of to-day, the deck chair has been relegated to a position of minor importance, and treatment has become highly technical, active, and operative, with collapse therapy requiring great manipulative dexterity and the aid of many ancillary services, not least those of the radiologist. The sanatorium has also become a centre of scientific research and of teaching—functions which require team-work in a large institution. The small, isolated building is, or should be, as dead as your Queen Anne.

LABORATORY ASSISTANTS

In a recent number of *Concours Médical* Dr. G. Lavalée takes exception to the growing custom of employing untrained young women as laboratory assistants. He would find a place here for the poor medical student who at present earns money by hawking patent medicines or even ushering cinema patrons into their seats in the intervals between lectures and examinations. Dr. Lavalée holds that where important verdicts depend on the accuracy, conscientiousness, and judgment of such assistants, the scientific sta of the laboratory has no right to cover unskille labour. This staff would doubtless have an answe ready—that supervision is vigilant, that procedure are checked at all stages, and that the interpretatio of a result by a medical student working in his spar time is no more likely to be accurate than one b a permanent member of a laboratory staff, howeve superficial is her knowledge of pathology. Dr Lavalée's plea for the employment of needy medica students in laboratories may impress their directors but surely not to the point of dismissing a singl competent employee.

IRELAND

(FROM OUR OWN CORRESPONDENT)

THE TASK OF THE HOSPITALS COMMISSION

A REPORT of the Irish Hospitals Commission was presented to the Minister for Local Government and Public Health early in the summer, but up to the present no information has been given as to its contents. The secretary of the commission has, however, addressed a letter to certain local authorities in which a little light is thrown on the present position of the commission's labours. He states that, in accordance with the Public Hospitals Act, 1933, a survey of hospital facilities in the Irish Free State is being made. The survey has been completed as regards voluntary hospitals, and much valuable information has been acquired. As no survey of hospital facilities would be complete without the inclusion of hospitals, infirmaries, and sanatoriums under the control of local authorities, the upkeep of which was provided mainly out of rates, a questionnaire is being issued, asking the average number of patients, number of beds, numbers admitted and discharged during the year, average cost, and other matters. The questionnaire has been designed to elicit information regarding all types of hospitals and institutions under the control of local authorities, which provide facilities for housing and treating the sick.

THE LATE DR. J. T. ELLIOTT

The death is announced of Dr. John Trimble Elliott, of Smithborough, the doyen of the medical profession of County Monaghan and one of the most respected of country practitioners in Ireland. Dr. Elliott qualified 54 years ago and has spent nearly all his professional life as dispensary medical officer of Smithborough. A modest and unassuming man, he had a fund of shrewd common sense which made his services much sought after on both professional and lay committees. He took an active part in medical organisation and was for many years a member of the council of the Irish Medical Association and honorary secretary for his county. He was also a strong supporter of the Royal Medical Benevolent Fund.

LLANELLY HOSPITAL.—The total income for this hospital last year was £11,809, the highest figure yet reached, and the patients admitted numbered 3809, an increase of 555 over the previous year. Expenditure amounted to £10,657, so that the excess of income over expenditure was nominally £1152, but actually after allowing for depreciation only £684. A new nurses' home is being built and, apart from equipment, will cost over £11,000.

PANEL AND CONTRACT PRACTICE

The Drug Habit

LAST year the average chemist's bill of an insured person was 2*s.* 11*d.*, a halfpenny less than in 1933. The curious thing is the extent to which this figure varies in different parts of the country. According to a report presented to the Association of Welsh Insurance Committees in session at Barmouth earlier in the month Manchester and Salford head the list with 4*s.* 10*d.* In his report for 1933 Sir George Newman mentioned the twenty insurance committee areas in England with the highest drug costs, stated in pence and decimals of a penny. In descending series these were: Manchester, 58·139; Salford, 57·863; Rutland, 50·027; Barrow-in-Furness, 49·031; Kingston-upon-Hull, 47·392; Oldham, 46·673; Preston, 45·887; Leeds, 44·654; Southend-on-Sea, 44·558; Blackburn, 44·000; Gateshead, 43·194; Stockport, 43·112; Liverpool, 42·500; South Shields, 42·475; Bury, 41·604; Birkenhead, 41·217; Newcastle-on-Tyne, 40·987; Birmingham, 40·849; Lancashire, 40·362; Cheshire, 40·224. It must excite surprise that such a health resort as Southend-on-Sea should be so high up on the list. London took fifty-third place with 35·75 pence per insured person, while the area in England with the lowest cost was Oxford with 21·99 pence. Districts though neighbours geographically may be found far apart in the tables: for instance, Gateshead 43 pence, Middlesbrough 29 pence; Kingston-upon-Hull 47½ pence, Grimsby 29½ pence. The figures for Wales varied from 21·14 pence in Radnor up to 36·62 pence in Caernarvon, the average for the principality being 32·19 pence. In Scotland, apart from Zetland where the cost was 45·1 pence, the most expensive area cost only 34·02 pence. But, lest it be assumed that insured persons in Scotland do not receive their fair share of physic, it should be recalled that in Scotland medicines required for the treatment of insured persons with tuberculosis are provided by the local authority and not out of the insurance committee's drug fund.

In Scotland too doctors have never adopted the custom of dispensing medicines for their patients and a bottle of medicine has not become the necessary corollary of a visit to the doctor. In England, for generations past, doctors with very few exceptions have dispensed all medicines for their wage-earning patients who have come to regard a visit to their doctor as synonymous with the receipt of medicine. As a result the cost in England of providing medicine per head of insured population regularly exceeds that in Scotland by approximately 50 per cent. Part of the increase in the cost of supplying medicine to the insured population is no doubt due to expensive forms of treatment such as insulin and liver extract, which have been introduced in recent years. The very fact that new methods of treatment are yearly being made available renders it incumbent on all concerned to utilise available funds to the best advantage. It will be observed that, among the first 20 places in order of expense, 11 are held by the county of Lancashire, probably a sequel to an old county custom for the household to have a standing account with the doctor on which an amount was paid weekly to a collector. They believed in a bottle of medicine and insisted on getting it and paying for it. When national insurance was first introduced suspicion of the Act caused many Lancashire people either to make no selection of doctor or to pay for their medicine through other sources. But when the economic depression came they had no option but to look to their insurance doctor for the medicine which they thought they required. Variation in prescribing cost might be due partly, as Sir George Newman has suggested, to the teaching of particular medical schools, and the adoption of these views in practice by students after qualification, but the examples of Lancashire and Scotland do not support that. What the Welsh association made of these figures we shall await with interest. At present there is no generally accepted explanation of the extraordinary variations in prescribing costs in comparable areas. There is also no evidence, so the late C.M.O. says, that in those areas where the habit of taking medicine is highly developed a more satisfactory standard of health has been achieved.

Tuberculosis in Wales

The importance of early notification of tuberculosis was emphasised by the chairman of the Welsh Board of Health, Mr. John Rowland, in an address to the Welsh Association of Insurance Committees. The success of the work of the Welsh National Memorial Association obviously depends on getting hold of cases in the early stages of the disease. The tuberculosis death-rate was, he said, steadily falling in Wales—the rate for 1934 was the lowest on record—but not as quickly as in England and Scotland, where the death-rate was 20 per cent. lower. Economic distress in the principality might have been one factor in retarding progress, but the greatest improvement had occurred, generally speaking, in the western counties of Wales, where tuberculosis mortality had always been high. In the subsequent discussion Mr. J. E. Tomley of Montgomery related some important evidence. The tuberculosis physician for Cardiganshire, after referring to the serious increase in the number of deaths from tuberculosis in that county, had, he said, admitted that out of a total of 61 deaths in 1934 there were 30 which had not been referred to the Association's officer. He also stated that in reply to the usual questionnaire no reason was given in 18 cases. In Montgomeryshire, on the other hand, there were no non-notified deaths, and the death-rate in that county was the lowest recorded. The report from Anglesey and Caernarvonshire showed that out of 206 persons who died from tuberculosis in that area during 1934 only 158 were seen by the Association during life, and 35 died of phthisis within three months of being first seen; a good proportion of these were insured persons, and the tuberculosis physician hesitated to credit the whole blame to the acuteness of the disease. The same seems to be true in measure of some other Welsh counties. The Association, through its individual insurance committees, is appealing to insurance practitioners for their help in the matter.

Surgical Spirit

Some confusion still exists in the minds of doctors and of chemists as to the effect of changes made by the Board of Customs and Excise in the regulations about surgical spirit. This cannot now be obtained over the chemist's counter. If a doctor wishes to obtain it for his patient he must issue a prescription requiring the chemist to provide Spiritus Antisepticus of the National Formulary or, alternatively, he may write out the prescription in full. The Ministry, after consultation with the Insurance Acts Committee, recently issued an explanation to both doctors and chemists which provides that where the term "surgical spirit" is used in a National Health Insurance prescription without qualification, it should be interpreted to mean the formula under Spiritus Antisepticus (Surgical Spirit) in the National Formulary, 1933.

The B.P. Codex, 1934, contains two formulæ for Spiritus Chirurgicalis B.P.C., and where a doctor orders Surgical Spirit No. 1 or Surgical Spirit No. 2 his intention has to be interpreted to mean formula No. 1 or formula No. 2 as the case may be. These formulæ were approved by the Board of Customs and Excise as from March 15th, 1934. Both formulæ contain industrial methylated spirit, castor oil, and diethyl phthalate. The former, in addition, contains methyl salicylate and the latter mineral naphtha. The difference between the two formulæ will be immediately obvious to the patient, and doctors have accordingly been advised carefully to specify in their prescriptions the particular formula they desire. In addition to the two forms of Spiritus Chirurgicalis there are also two forms of industrial spirit—namely, Spir. Meth. Indust., B.P., 1932, and Spir. Meth. Indust. sine Aceton., B.P.C., 1934. Practitioners are reminded that the latter preparation is preferable for surgical purposes, as it is compatible with iodine. The former, when brought into contact with iodine, produces an irritating compound by reaction between the iodine and acetone.

To put the position briefly, prescriptions will be interpreted as follows: Surgical Spirit=Spiritus Antisepticus (N.F.). Surgical Spirit No. 1=Spiritus Chirurgicalis, B.P.C., 1934, formula No. 1. Surgical Spirit No. 2=Spiritus Chirurgicalis, B.P.C., formula No. 2. It is hoped that the next edition of the National Formulary will provide that in the absence of any directions from the prescriber Surgical Spirit No. 1 shall be dispensed when surgical spirit is prescribed. Further, it will probably be laid down that acetone-free industrial methylated spirit shall be used for all formulæ unless otherwise directed by the prescriber. Unless and until such provision is made, however, the position will be as here indicated.

OPENING OF THE MEDICAL SCHOOLS

IN connexion with the opening of the session at the London medical schools the following arrangements have been made :—

Charing Cross Hospital

A post-graduate course for former students will be held on Oct. 5th and 6th. The annual dinner will take place at the Café Royal at 8 P.M. on Saturday, Oct. 5th, with Rev. A. W. Oxford, M.D., in the chair. On Friday, Oct. 25th, at 4 P.M., Sir Kingsley Wood will distribute the prizes and deliver an address.

Guy's Hospital

On Tuesday, Oct. 8th, at 3 P.M., Sir Kingsley Wood will deliver the inaugural address. The biennial dinner will be held at the Connaught Rooms, Great Queen-street, W.C., on Nov. 15th at 7 P.M., with Mr. A. W. Ormond in the chair.

King's College Hospital

On Saturday, Oct. 5th, from noon to 6 P.M., and on Sunday morning there will be lectures and demonstrations open to all practitioners. Post-graduate lectures on tuberculosis will also be delivered in the lecture theatre of the medical school on Thursdays at 9 P.M. from Oct. 3rd onwards. The annual dinner of past and present students will be held on Oct. 5th at the Mayfair Hotel at 8 P.M., with Sir Charlton Briscoe in the chair. On Oct. 10th Dr. G. F. Still will deliver the inaugural address.

London Hospital

A post-graduate course for former students of the hospital will be held from Oct. 16th to 19th. The old students' dinner will be held on Thursday, Oct. 17th, at 7.30 P.M., at the Trocadero Restaurant, with Prof. H. M. Turnbull in the chair.

Middlesex Hospital

A post-graduate course for former students of the hospital will be held from Sept. 28th to Oct. 1st. On Oct. 1st the annual dinner will be held at the Savoy Hotel at 7.30 P.M., and Dr. H. Campbell Thomson will be in the chair.

Royal Free Hospital

On Tuesday, Oct. 1st, at 3 P.M., the inaugural address will be delivered by Sir Walter Moberly. The annual reunion dinner of the old students will be held on Nov. 28th at the Savoy Hotel, when Dr. Letitia Fairfield and Commander Stephen King-Hall will be among the guests of honour.

St. Bartholomew's Hospital

On Tuesday, Nov. 5th, the old students' dinner will be held at 8 P.M. in the College Hall, Charterhouse-square, with Mr. W. Girling Ball in the chair. The Prince of Wales will be present.

St. George's Hospital

On Wednesday, Nov. 13th, Lord Macmillan will give an address at the annual prize-giving which will be held in the board room at 3 P.M. The annual dinner will take place the same evening at Claridge's Hotel at 7.30 P.M.

St. Mary's Hospital

A week-end post-graduate course will be held from Sept. 27th to 29th, open to all medical practitioners without fee. The annual dinner of past and present students will take place at Claridge's Hotel on Sept. 28th at 7.30 P.M., with Dr. Duncan Fitzwilliams in the chair.

St. Thomas's Hospital

Sir Cuthbert Wallace will preside at the old students' dinner, which will take place at the Dorchester Hotel at 7.45 P.M. on Oct. 4th.

University College Hospital

On Tuesday, Oct. 1st, at 4 P.M., a reception will be held in the library of the medical school. The annual demonstrations for old students will take place on Oct. 10th and 11th, and the annual dinner will be held in the library of the medical school on Oct. 11th at 7.30 P.M., with Sir George Welch in the chair. The annual dinner of the Women's Association will be held at the Piccadilly Hotel, W., at 8 P.M., on the same day, and Dr. Annis Gillie will preside.

Westminster Hospital

On Monday, Sept. 30th, at 3 P.M., the winter session will open at the Caxton Hall, Westminster, when Major Ian Hay Beith will deliver the inaugural address. He will speak on the Privileged Profession. A short course, open to all medical practitioners, will be held on Sept. 28th and 29th, and the annual dinner of past and present students will take place at the Trocadero Restaurant on Saturday, Sept. 28th, when Dr. Vivian Orr will be in the chair.

Royal Dental Hospital

Prizes will be distributed at the hospital on Friday, Oct. 4th, at 8 P.M., at a conversazione at which Sir Francis Acland will preside. The annual clinical At Home will be held at the hospital on Nov. 23rd, and the dinner of past and present students will take place on the same evening at the Trocadero Restaurant, at 7.30 P.M., with Mr. Herbert Smale in the chair.

Further details of post-graduate courses will appear in due course in our *Medical Diary*.

CORRESPONDENCE

VACCINATION ON THE THIRD DAY

To the Editor of THE LANCET

SIR,—*I am writing to draw attention to the harm* which so often results from vaccination during the first three weeks of an infant's life. The infant is struggling, at this time, to adjust itself to its surroundings, and it is only with care and help that a steady gain in weight, and normal adjustment, can be maintained. It has long been the custom to punctuate this trying first month by first a circumcision and then vaccination. The number of infants' lives which have been lost as a result of these two procedures must be very large.

I am informed that it is the custom at one large maternity hospital to vaccinate infants on the third day, as a routine. Baby S. was born at that hospital on August 21st, vaccinated on August 24th, became deeply jaundiced on August 26th and 27th, with an enlarged liver and spleen, and was admitted to Great Ormond-street, under my care, on the tenth day after birth. The child had a fever, a tremendous reaction to the vaccination on the left arm, the stools were unhealthy, and the blood showed a marked hæmolytic anæmia. As the vaccination subsided, the liver and spleen grew smaller, the temperature dropped, and the baby commenced to gain weight.

Surely this pernicious practice of adding to the baby's difficulties deliberately, by such early vaccination, should be widely condemned? Although I am completely in favour of vaccination, I think that three or four weeks of age, in a perfectly normal healthy infant, should be the very earliest time for this, and very often it should be left still later, until the gain in weight is definitely assured and the baby doing well.—I am, Sir, yours faithfully,

DONALD PATERSON.

Devonshire-place, W., Sept. 11th.

PERFORATION OF THE ŒSOPHAGUS BY A SWALLOWED FOREIGN BODY

To the Editor of THE LANCET

SIR,—The following case is of interest in view of the paper on this subject by Mr. John E. G. McGibbon in your last issue.

In July, 1934, a girl of 5 attended with a history of having swallowed a fish-bone four days previously. She had been seen at another hospital immediately after, but nothing was apparently detected or done. Since then there was dysphagia, and the child could not swallow at all on account of the pain and the obstruction. Her head was held rigidly to the left side (as in acute torticollis) with pain on that side of the neck low down, over the cricoid region, where an area of tenderness could be defined. There was no palpable cervical swelling. The patient was coughing up pus and was ill. The temperature was 103° F. On mirror laryngoscopy there was a collection of pus behind and over the larynx. Clinical and radiological examination of the chest was negative. X ray of the œsophagus revealed no foreign body. A bismuth swallow passed down without any hitch.

Under general anæsthesia, preceded by a preliminary premedication with rectal paraldehyde, an endoscopic examination was carried out. The larynx was normal, but fœtid pus welled up from the hypopharynx. There was no retropharyngeal abscess. The œsophagoscope was introduced for about one inch below the cricoid. The pus—fœtid and in large amount—was completely removed. It originated from a retro-œsophageal abscess and entered the œsophagus through a punctured wound, marked by granulations, in the posterior wall. The abscess was emptied by gentle pressure of the beak of the œsophagoscope.

A large rigid spiked fish-bone jutted out for about half an inch, in an antero-posterior direction, from the perforation in the œsophagus. When gripped with forceps it could not be moved, being apparently firmly impacted. The grip on the bone was released. By the time an immediate second attempt was made to grip this bone it had completely disappeared. At this stage no further pus was present in the œsophagus or in the retro-œsophageal abscess. The manipulations lasted 20 minutes.

The sudden and complete disappearance of the bone in view of the impaction was mystifying. It was never traced, though the fæces were examined subsequently. Convalescence was uneventful, and within a week the child left the hospital. When seen about six months later she had remained well.

I am, Sir, yours faithfully,

London, W., Sept. 14th. N. ASHERSON.

BACTERIOLOGY OF RHEUMATISM

To the Editor of THE LANCET

SIR,—Dr. Poynton has inspired all those who learned at his knee with affection and respect, and I would not lightly attempt to detract in the least from his just claim that he and Dr. Paine were the first to grow in pure culture the diplococcus of rheumatism, but in June, 1887 (Brit. Med. Jour., i., 1381), Dr. A. Mantle states:—

> A typical case of acute rheumatism being under his care, under strict aseptic precautions, and by means of a sterilised hypodermic syringe, about a drachm of serum was withdrawn from the knee-joint. Several sterilised tubes of gelatinised meat infusion were at once inoculated and in each tube a copious growth took place. . . . He had found two kinds of bacteria, a micrococcus and a small bacillus. Cover-glass preparations of blood and serum showed micrococci as single cocci or pairs (diplococci).

Dr. Mantle found a variety of organisms in various cases and he figures these in illustrations in this article, but it seems to me that the quotation from his original communication confirms my statement in the Ingleby lecture that Dr. Mantle reported a growth of diplococcus from a case of rheumatism.

I am, Sir, yours faithfully,

Edgbaston, Sept. 11th. K. DOUGLAS WILKINSON.

MALARIA AND RACIAL EXTINCTION

To the Editor of THE LANCET

SIR,—The *Ceylon Observer* of July 6th, under the title "Wiped out by Malaria?" refers at some length to my paper on The Muruts of North Borneo in your issue of May 25th, and to your comment upon it. The *Observer* draws a comparison between the problems of malaria and depopulation in Ceylon and in North Borneo, and concludes that in Ceylon, where conditions are more favourable, there is no danger of the increase in population becoming permanently arrested as a result of the recent malaria epidemic. This view is based to some extent on the theory that primitive races have a tendency to languish. But while this may apply to small isolated tribes, such as tree Negritoes or Sakais, it seems to me unnecessary to invoke such imponderable influences when other factors are so obvious.

In brief but illuminating phrases the *Observer* gives a vivid insight into the terrible results of a mass infection of a non-immune population with virulent strains of malarial parasites:—

> "Appalling . . . ravages. . . . The number of deaths a month has indeed been large enough to justify some of the scare headings in the sensationalist sections of the London Press . . . whole families wiped out and many a village left with no more than a single child in it. . . ."

The Murut tribes of Borneo endured such a saturation infection (the Germans call it *Durchseuchung*) some eight to ten years ago, since when their numbers have progressively declined, until now I doubt if more than 12,000 are left of the 22,000 numbered in the 1931 census. In my opinion they would have suffered far less, and their numbers would have been maintained, had they been spared what is nothing less than quinine deprivation from the very outset of their first new infection. That these unfortunate but trusting and obedient natives should make long journeys in the hope of obtaining vital supplies of quinine and dressings, only to be put off with two or three quinine capsules, a small strip of lint, one-third of a bandage, and a little liniment in the palm of the hand is very pathetic, and it was distressing to have to refuse them an adequate supply of quinine.

The Muruts are interesting to ethnologists, and they are even capable of performing useful labour on estates, when they have received proper treatment for splenomegaly, hookworm, and lesser complaints. Governments would seem to become interested in their aboriginal peoples sometimes only when it is too late to save them, and the Muruts are still going through the stage of being interesting only for revenue purposes. The alternatives to the annual ungraduated cash poll-tax of $1.00—i.e., 2*s.* 4*d.*—for every male adult are (1) payment of a fine of five times the tax, (2) two weeks' rigorous imprisonment, (3) "voluntary" heavy work as coolie bearers for three days, for which they must bring their own food. The imposition of poll-tax on a declining population *must* accelerate the decline. I am, Sir, yours faithfully,

Whiston-street, E., Sept. 9th. A. J. COPELAND.

BILIARY DRAINAGE

To the Editor of THE LANCET

SIR,—I was specially interested in one observation made in the article on biliary drainage by Dr. T. Hunt in THE LANCET of last week. He says that the introduction of magnesium sulphate directly into the duodenum is almost always followed by a flow of bile from the common bile-duct. If this bile is removed by tube there is seldom diarrhœa (the magnesium sulphate presumably remains in the intestines). This observation adds weight to a theory as to the mode of action of magnesium sulphate which I mentioned in THE LANCET of Jan. 26th, and also mentioned by Dr. Hunt last week in his article. I suggested that it depended on the increased flow of bile which follows its administration by mouth.

The purgative action of magnesium sulphate has been proved not to be due to its effect after absorption into the general circulation. It is not due to its osmotic effect because Dr. A. F. Hurst has shown that the watery stool does not contain an excess of sulphate. Also if charcoal is given by mouth a short while before the sulphate the charcoal does *not* appear in the stool which follows. I find that if fresh bile is given by mouth it acts as a strong purgative and preparations of bile salts which are given with the object of causing a greater flow of bile frequently give rise to diarrhœa. Also fresh ox bile given per rectum increases peristalsis in cases of ileus.

These facts suggest that the chief effect of magnesium sulphate may be an increased peristalsis of the large intestine following an increased flow of bile.—I am, Sir, yours faithfully,

D. LINCOLN LEWIS.

Archway Hospital, Highgate, Sept. 17th.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDE SEPT. 7TH, 1935

Notifications.—The following cases of infectiou disease were notified during the week: Small-pox, 0; scarlet fever, 1924; diphtheria, 1003; enteric fever, 85; acute pneumonia (primary or influenzal), 336; puerperal fever, 36; puerperal pyrexia, 131; cerebro-spinal fever, 14; acute poliomyelitis, 18; polio encephalitis, 1; encephalitis lethargica, 8; dysentery 12; ophthalmia neonatorum, 89. No case of cholera, plague, or typhus fever was notified during the week

The number of cases in the Infectious Hospitals of the Londo County Council on Sept. 13th was 2641, which included: Scarle fever, 794; diphtheria, 949; measles, 44; whooping-cough 403; puerperal fever, 32 mothers (plus 13 babies); encephaliti lethargica, 271; poliomyelitis, 14. At St. Margaret's Hospita there were 21 babies (plus 3 mothers) with ophthalmi neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox or enteric fever, 4 (0) from measles, 2 (0) from scarlet fever, 14 (4) from whooping-cough, 22 (3) from diphtheria, 67 (3 from diarrhœa and enteritis under two years, an 17 (2) from influenza. The figures in parentheses ar *those for London itself.*

Deaths from [illegible] is were distributed ove 28 *great towns* [illegible] ers being *Liverpool* 10, Nottingham 8, [illegible] 5, Manchester 4, Leed and Sunderland [illegible] reat town more than 2 Birmingham rep [illegible] measles. Four cases o diphtheria proved fatal at Manchester, 2 at Bradford.

The number of stillbirths notified during the week was 268 (corresponding to a rate of 45 per 1000 *total births*), including 50 in London.

MEDICAL NEWS

King's College Hospital

The Duke of York has accepted the presidency of King's College Hospital in succession to the Duke of Connaught.

A *Victorian centenary* loan exhibition is being planned for the year 1937 to celebrate the centenary of the accession of Queen Victoria. The exhibition will be mainly illustrative of women's activities during the reign. The proceeds will be given to the hospital, which was founded two years after Queen Victoria's accession.

Society of Apothecaries

Sir William Willcox has been elected the new Master of this society and Mr. A. P. Gibbons and Mr. Hugh Lett Wardens.

Society for the Study of Inebriety

The next meeting of this society will be held in the rooms of the Medical Society of London (11, Chandos-street, London, W.) on Tuesday, Oct. 8th, at 4 P.M., when Dr. Gerald Slot will open a discussion on the medico-legal *aspects of drunkenness.*

Society of Public Analysts

A meeting of this society will be held on Wednesday, Oct. 2nd, at the rooms of the Chemical Society, Burlington House, Piccadilly, London, W., at 8 P.M. The papers *to be read include one on* the chemical examination of furs in relation to dermatitis (identification of vegetable and other dyes) by Mr. H. E. Cox, D.Sc.

Wireless Sets for Hospitals

The King and Queen have given £150 to the fund to equip voluntary *hospitals* in Scotland with wireless sets.

British Red Cross Society

Two courses *of lectures* and demonstrations on anti-gas precautions and first aid for air-raid casualties will be held *at the County of London headquarters* of this society, 9, Chesham-street, S.W., on Fridays, one at 2.30 and another at 8 P.M. from Oct. 4th onwards. Each course consists of seven lectures and demonstrations. Applications for tickets should reach the county secretary of the branch not later than Sept. 28th.

Mr. Wilfred Trotter, F.R.S., will deliver a Lloyd Roberts lecture on General Ideas in Medicine at the Royal Society of Medicine on Monday, Sept. 30th, at 5 P.M.

Charing Cross Hospital

On Thursday, Nov. 28th, at 5 P.M., Prof. Edward Mellanby, F.R.S., will deliver the Huxley lecture in the medical school. Invitations may be obtained on application to the secretary of the school.

Royal Eye Hospital

A research scholarship tenable at this hospital is shortly to be awarded. Preference will be given to a candidate who proposes to undertake research on a clinical subject. Further particulars will be found in our advertisement columns.

Food Poisoning at Swansea

On Thursday of last week a thousand children were entertained to a feast in the Market Hall, Swansea, by the transport company's employees, and more than 150 of these children suffered from acute gastric disturbance, although only one child, a girl of 13, needed hospital treatment. The suspect article of food was fresh minced meat presented by local butchers, samples of which are being examined by the pathologist of Swansea Hospital.

Leeds Public Dispensary and Hospital

A series of post-graduate lectures, open without fee to all members of the medical profession, will be given during the winter. They will be held every Wednesday at 4 P.M. at the dispensary, and the following members of the honorary staff will take part: Mr. A. D. Sharp, Mr. A. Gough, Dr. H. H. Moll, Dr. S. J. Hartfall, Dr. H. G. Garland, Mr. L. N. Pyrah, and Dr. H. B. Pope. Particulars of the course will appear weekly in our Medical Diary.

Mental Health Congress

The fourth biennial conference on mental health arranged by the National Council for Mental Hygiene will be held at the Caxton Hall, Westminster, London, S.W., from Jan. 23rd to 25th, and will be opened by the Duke of Kent. The subjects which will be discussed include mental hygiene and international relations, the organisation and correlation of mental health services in local areas, problems of marriage and the establishment of courts of domestic relations, and the priest and the doctor in the treatment of nervous and mental disorders. The last day will be devoted to a discussion of Education for Living under the following headings: Mental Health; Those First Eight Years; "Moulding" the Mind: Eight to Fourteen; The "Finished" Product: Fourteen Onwards. The secretary of the council may be addressed at 78, Chandos House, Palmer-street, London, S.W.1.

Medical Diary

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ST. MARY'S HOSPITAL, W.

Friday, Sept. 27th.—10.15 A.M., Dr. D. H. Brinton: Some Common Neurological Problems of General Practice. 11 A.M., Mr. Leslie Williams: Hormone Therapy in Gynæcology. Noon, Dr. A. F. Hurst: Some Functional Disorders of Digestion. 2.15 P.M., Dr. A. Hope Gosse: Electrocardiograms. 3.15 P.M., Mr. R. M. Handfield-Jones: Diagnosis and Treatment of Urinary Calculi. 4.15 P.M., Dr. Duncan Fitzwilliams: The Modern Treatment of Carcinoma of the Breast.

Saturday.—10.15 A.M., Dr. T. C. Hunt: Popular Remedies, New and Old. 11 A.M., Mr. Aleck Bourne: Has Antenatal Care Failed? Noon, Dr. Reginald Miller: Slimming Problems. 2.15 P.M., Mr. V. Zachary Cope: Four Symptoms in Search of an Author. 3.15 P.M., Dr. H. Courtney Gage: X Ray Diagnosis of Organic Lesions of the Alimentary Tract.

Sunday.—10.15 A.M., Mr. A. Dickson Wright: Diagnosis and Treatment of Minor Rectal Condition. 11 A.M., Dr. C. M. Wilson Medical Reasons for Terminating Pregnancy. Noon, Prof. Henry Cohen: Parkinsonism. (Open to all medical practitioners without fee.)

MIDDLESEX HOSPITAL.

Saturday, Sept. 28th.—2.30 P.M., Dr. B. W. Windeyer: Types of Cases Suitable for Radium Therapy. 3.45 P.M., Dr. H. L. Marriott and Dr. A. Kekwick: New Method for Continuous Transfusion of Saline or Blood.

Sunday.—10.15 A.M., Dr. A. A. Moncrieff: Measures for Prevention of Specific Fevers. 11.15 A.M., Mr. D. H. Patey: Recent Advances in Diagnosis and Treatment of Intestinal Obstruction. 12.15 P.M., Mr. R. Affleck Greeves: Treatment of Conjunctivitis and Other Common Eye Conditions. (For former students of the hospital.)

WESTMINSTER HOSPITAL.

Saturday, Sept. 28th.—10 A.M., Mr. A. Tudor Edwards and Dr. W. E. Lloyd: Treatment of Pulmonary Tuberculosis. 11.45 A.M., Dr. R. J. V. Pulvertaft and Dr. N. F. Maclagan: Diabetes.

Sunday.—10.15 A.M., Dr. Adolphe Abrahams: The Physical and Psychological Basis of Disease. 11.15 A.M., Dr. Reginald Lightwood: Some Practical Points in the Diagnosis and Treatment of Disease in Childhood. 12.15 P.M., Mr. Stanford Cade: The Earlier Diagnosis of Accessible Cancer. (Open to all medical practitioners.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, Sept. 23rd, to Saturday, Sept. 28th.—Westminster Hospital, S.W. All-day course in medicine and surgery.—Brompton Hospital, S.W. All-day course in chest diseases.—Royal Westminster Ophthalmic Hospital, Broad-street, W.C. Sat. and Sun. course in ophthalmology.—Courses are open only to members and associates of the Fellowship.

ROYAL INFIRMARY, MANCHESTER.

Tuesday, Sept. 24th.—4.15 P.M., Dr. Charles S. D. Don: High Blood Pressure.

Friday.—4.15 P.M., Mr. D. L. Sewell: Demonstration of Malignant Disease of the Nose and Throat treated by Radium.

Births, Marriages, and Deaths

BIRTHS

Mitchell.—On Sept. 9th, the wife of S. F. Mitchell, M.R.C.S. Eng., of Beckley, Sussex, of a daughter.

Muir.—On Sept. 17th, at Hull, the wife of David Clark Muir, M.D., F.R.C.P., of a son.

Oakden.—On Sept. 8th, at Cambridge, the wife of G. F. Oakden, M.B. Camb., of a daughter.

Robinson.—On Sept. 9th, at Kingston-on-Thames, the wife of R. D. Robinson, M.B. Lond., of a son.

MARRIAGES

Beattie—Baddeley.—On Sept. 11th, at Reigate, William John Hunt Montgomery Beattie, M.D. Camb., F.R.C.S. Eng., to Marjorie Gertrude, only daughter of Mr. Bernard Baddeley, Reigate Heath, Surrey.

Braithwaite—Fawcett.—On Sept. 7th, at St. George's, Campden Hill, Edward Braithwaite, B.M. Oxf., of Egremont, Cumberland, to Barbara Fawcett, of Cawsand, Devon.

Goldsmith—Oliver.—On Sept. 9th, at Wood Green Congregational Church, Edward J. Goldsmith, M.R.C.S. Eng., of Allestree, near Derby, to Ivy E. Oliver, M.R.C.S. Eng., of Wood Green, London.

Gurney—Moule.—On Sept. 10th, at St. Peter's Church, Limpsfield, Theodore Ronald Valpy Gurney, M.B. Brist., to Agnes Mary Riddell, only daughter of Mr. and Mrs. W. Moule, of Brighton.

Holgate—Gamon.—On Sept. 11th, at Halton, Albert William Holgate, M.S. Lond., F.R.C.S. Eng., of Chester, to Monica Taylor Gamon, of Halton, Cheshire.

Marshall—De Mierre.—On Sept. 10th, at Hellingly Parish Church, Sussex, George Hay Marshall, F.R.C.S. Edin., to Helen Mary (Jill), second daughter of Mr. A. De Mierre, of Hellingly.

Matthew—Cound.—On Sept. 7th, at St. Theodore's Church, Port Talbot, Patrick Crichton Matthew, M.R.C.S. Eng., to Catherine, youngest daughter of the late Mr. Alfred Cound and Mrs. Cound, Port Talbot.

GOLDEN WEDDING

Fortescue Fox—McDougall.—On Sept. 16th, 1885, at the Jameston Church, Strathpeffer, by the Rev. James Calder McPhail, D.D., Pilrig, Edinburgh, Robert Fortescue Fox, M.D., seventh son of Joseph John Fox, Surgeon, of Stoke Newington, to Katharine Stewart McDougall, daughter of the Rev. W. S. McDougall, Strathpeffer.

DEATHS

Duncan.—On Sept. 15th, at Afton, Woking, William Duncan, O.B.E., M.B. Glasg., a senior medical officer of the Ministry of Health.

Edginton.—On Sept. 12th, at Walton St. Mary, Clevedon, Somerset, Robert William Edginton, M.D. Brux., M.R.C.S. Eng., aged 85.

MacBean Ross.—On Sept. 16th, at Portsmouth, Donald Charles, dearly beloved elder son of Doctor and Mrs. J. N. MacBean Ross, of Lauriston, Sutton, Surrey.

McMaster.—On Sept. 8th, suddenly, at 7, Forestdale, Southgate, London, N.10, Archibald Cotterell McMaster, M.D., F.R.C.S. Edin., late of Rugby.

Richards.—On Sept. 12th, suddenly, at Odiham, Hants, Robert Richards, L.R.C.P.I., L.R.C.S. Edin., aged 72.

Winslow.—On Sept. 8th, at North Stoke Mill, Oxford, Walter Winslow, M.B., B.Chir. Camb.

Worthington.—On Sept. 14th, at Warwick, Sidney Worthington, M.D. Lond., F.R.C.S. Eng., aged 76 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

A PROPOSED NATIONAL OXYGEN TENT SERVICE

THE British Red Cross Society has received the following memorandum from members of the staff of all the London teaching hospitals:—

"We who have signed this letter are convinced that the oxygen tent provides the most efficient means of administering oxygen so far devised, and is of great value in a number of medical and surgical conditions. We should welcome any steps to make the method more readily available in hospitals and in the patient's own home. We believe that any help the British Red Cross Society can give in this connexion will be for the public welfare."

The signatories to this memorandum are Lord Dawson of Penn (London), Lord Horder and Sir Thomas Dunhill (St. Bartholomew's), G. E. Beaumont and R. A. Young (Middlesex), A. Tudor Edwards (Westminster), Douglas Firth (King's College Hospital), Francis R. Fraser (Postgraduate Medical School, Hammersmith Hospital), Reginald Hilton (St. Thomas's), Gordon Holmes (Charing Cross), Arthur F. Hurst and E. P. Poulton (Guy's), Cecil A. Joll (Royal Free), Reginald Miller (St. Mary's), Wilfred J. Pearson (University College Hospital), and James Torrens (St. George's).

The British Red Cross Society has decided to respond to this memorandum by coöperating in the establishment of a national oxygen tent service should it be found that there is need for such a service. Before embarking on a complete scheme, which would involve considerable expense, the society desires to collect more definite data than is at present available on the value of the apparatus in various conditions. In order to obtain this evidence the society has placed an order for the construction of twelve sets of apparatus, which will probably be completed before the end of October. One tent will then be placed at the disposal of each of the hospitals to which the signatories to the memorandum are attached (except the Hammersmith Hospital which already has one), the initial cost being met out of the funds of the society.

The hospitals have been asked whether they are willing to accept one of the tents for trial over a period of not less than two months, keeping comprehensive records of the cases for which it has been used, and furnishing a report at the end of the period on the value and desirability of a national service. If at the end of the trial any hospital wishes to acquire the apparatus it can do so on refunding the cost of the tent to the society.

As some instruction is desirable as to the operation of the apparatus, a model will be at the house of the British Red Cross Society, 14, Grosvenor-crescent, London, S.W.1, and will be available for demonstration to members of the staff of the hospitals by appointment after Oct. 1st.

The bed tent for administering oxygen and carbon dioxide, described by Dr. E. P. Poulton and illustrated in our columns two years ago (see THE LANCET, 1933, i., 245), has since been modified in important details. It has been found possible to abandon the cumbersome extension ladders on either side of the bed, with the crossbar from which the tent was suspended. The modern tent is built on an adaptable frame and can be raised or lowered by means of a handle behind the bed. The provisions for keeping the patient under full observation through non-inflammable celluloid windows, and for keeping him dry and cool, have also been improved. It seems likely that the hospitals concerned will gratefully accept the offer of the British Red Cross Society. If the verdict is favourable, the next step may be the organisation of a hire service for oxygen tents under the auspices of the society.

REGIUS CHAIR OF PHYSIC AT CAMBRIDGE

A CORRESPONDENT writes: "Your note on the appointment as the twenty-first regius professor of physic at Cambridge of Dr. John Ryle, physician to Guy's Hospital, raises some points of interest. The chair was founded in 1540, and until 1892, when Sir Clifford Allbutt was appointed, had almost always been occupied by a local physician resident in Cambridge. Before Allbutt's appointment, Sir Andrew Clark, then president of the Royal College of Physicians of London and also of the Royal Medical and Chirurgical Society, was asked by some members of the medical faculty at Cambridge if he would accept the chair, but he declined. So although Dr. Ryle is the first regius professor not a Cambridge man by education, the idea of introducing such entirely fresh blood is more than forty years old. Under the new statutes all Cambridge professors appointed after Oct. 1st, 1924, vacate their office and automatically become Emeritus professors at the end of the academic year in which they attain the age of 65 years. Before this change was insti tuted by the Royal Commission, the only limit was that of life, and 5 of the 18 professors of physi under the old statutes remained in office when 80 or more years had passed over their heads; one indeed was 90, and Sir Clifford Allbutt, who neve grew old in mind, was 89 years of age. Two professor with tenures of 52 and 41 years practicall monopolised the whole of the eighteenth century.

"On the other hand, two others—the second John Hatcher, and the ninth, Ralph Winterton—held the chair for one year only. It was he wh as a mathematician had suffered from sleeplessness an melancholia and consulted the then regius professo of physic, Dr. John Collins; this professor advise him to give up mathematics and to study medicin assuring him that he might thus erase from h mind the recollection of past ills. 'I did,' sai Winterton in the preface to one of his books, 'as h advised, and what he foretold took place.' Winterto was a most eminent scholar, but unfortunately di in his thirty-seventh year in 1636. His successor w far the most distinguished occupant of the cha before the nineteenth century—namely, Franc Glisson, anatomist, physiologist, pathologist, phys cian, pioneer in orthopædics, and philosopher. I was in the regius chair for the remaining 31 yea of his life, but was much of an absentee first duri the Civil War when he practised at Colchester wi great success, and also, but especially later, London where he held many offices, including th of president, at the Royal College of Physicia of president, at the Royal College of Physicia was one of the original Fellows of the Royal Societ and did yeoman's service during the great plag He probably also found the intensely Royali atmosphere at Cambridge distasteful. Caius, senior, was also president of the college, but n regius professor; both of them died in London.

"The posts of regius professor of physic and th of regius professor of medicine at the senior universi are high in honour, ranking next to the usual more temporary presidents of the two Royal Colleg It is fortunate to be able to fill such a post und the new conditions with one who is in every w eligible and is also young enough to have the prosp of holding it for a considerable period. With popular medical school of 500 students engaged pre-clinical work under the best possible conditio the possibility of the Cambridge School ever becomi 'complete'—namely, supplying clinical facilities a satisfactory character to all these students—is mo remote than ever from practical politics. Half century ago teachers in all the clinical subjects w appointed, and the ambitious plan of a compl medical school was more than a dream at any r to the first-named of the great triumvirate— George Humphry, Sir George Paget, and Sir Mich oster—to whom the medical school is so largely debted for its present efficiency and fame.

“Cambridge is the home of research, and realisation f the need for an adequate department there of linical science with facilities for research is not ew; Oxford has been more fortunate in being able o set this example to the younger university. The dvantages of a scheme whereby young medical raduates could carry out investigation on clinical roblems in selected cases under the guidance of an ctive director and in close touch with the fine boratories of anatomy, physiology, biochemistry, nd pathology are too obvious to justify more rgument; but there is thus an opportunity for a ell-advised benefactor to set going a department hich should fully show the great value of such enerosity.

“The new regius professor is imbued with the raditions of Guy's Hospital, and the example of ddison, Bright, and Hodgkin and many others; ndeed it is perhaps remarkable, and certainly a ropitious omen, that there is now for the first time his link between that great hospital and the ambridge medical school.”

SOME HOSPITAL PHARMACOPŒIAS

THE introduction of the B.P. 1932 has necessitated the revision of many hospital pharmacopœias and ther publications concerned chiefly with official rugs. Three such pharmacopœias are those of King's College, St. Mary's, and Westminster Hospitals, all of which have been brought up to date and issued as 1934 editions. There are many features in common and numerous familiar formulæ are included in each, but it is interesting to note certain individual tastes in prescribing.

At King's there is a cataplasma carbonis, consisting of crushed linseed and wood charcoal; morphine acetate, a relatively unstable salt of morphine, is retained in *Collut. Morphinæ;* ergotamine tartrate is prescribed as an injection which is given the name of *Injectio Ergotæ;* chiretta is used as the bitter in *Mist. Acid. Hydrochlor.;* Unna's paste contains 2 per cent. of ichthammol; pills are featured and only two formulæ for tablets are given.

At St. Mary's we find *Gutt. Duboisin. Sulphat.*, *Inj. Lithii Salicyl.* for varicose veins and, although liquid extract of ergot, B.P. 1932, gives an unsightly deposit on admixture with water, formulæ are given for *Mist. Ergot. Acid.* and *Mist. Ergot. Alk.* Chloramine T is used in the preparation of *Inj. Chloraminæ*, a preparation much superior to the hypochlorite solutions on account of its stability. In the list of proprietary preparations two mistakes call for comment. Radiostoleum (it should be Radiostol) is given as the synonym for *Liq. Ergosterol. Irradiat.*, and a more serious mistake is Medinal for soluble phenobarbitone, instead of soluble barbitone.

Westminster has a number of medicated papers—e.g., *Charta Potass. Nitrat.* *Enema Rutæ* is retained and an unusual mixture in the children's formulary is *Mist. Ichthammolis.* This pharmacopœia shows evidence of improved formulæ in the introduction of elix. cascaræ in *Mist. Casc. Sagr.*, the use of light liquid paraffin in the preparation of nebulæ, and physostigmine salicylate in *Gutt. Physostigm.*

All three of these hospital pharmacopœias contain data and tables of value to the hospital student and the practitioner.

CHILD DEVELOPMENT

AN ambitious attempt to portray the development of the child from its earliest infancy to full adult growth which, she assumes, is reached at the early age of 17 years, has recently been published by Prof. Charlotte Bühler.[1] She has tried by means of direct observation and experiment to evaluate the development of traits in the intellectual, emotional, and social spheres. We have every sympathy with the desire to obtain more definite estimates of the normal evolution of children, while hesitating to accept any estimate based on such figures as are here presented. The collection of cases from which conclusions are drawn is inadequate and the generalisations made do not bear scrutiny. Dr. Bühler does not give all the figures on which she bases her statements; but we quote two which she does mention to show how narrow is the viewpoint from which she has worked. The first is the estimate of the reactions of very young infants: “the cross-section was arrived at by studying five healthy children for each month of the first year for one day and one night.” At the other end of the scale her estimate of the characterological constants of children is based on a study of only 20 families, and by means of the visits of a psychologist to a family twice a week for one to two hours, with a subsequent “write up” of impressions, it being tacitly assumed that the reactions of the family were normal in the presence of the guest. Dr. Bühler apparently has little use for the psychological tests accepted in this country, the revised Terman, the Binet-Simon, the Merrill-Palmer, the Gesell tests, because they are designed to test only intellectual ability. This is certainly not true of the Gesell and Merrill-Palmer tests, and in any case if Dr. Bühler had studied some of the psychological reports submitted in the child guidance clinics in this country she would have found the formal report of the estimated I.Q. almost invariably accompanied by a comment on those emotional and social reactions of the child which might modify the intelligence estimate. Incidentally all the accepted tests are based on groups of more than 600 cases, and have been revised and adapted to fit the particular types of children for whom they are used, so that inaccuracies dependent on such factors as race or environment may be eliminated. Apart from the unsatisfactory figures on which the conclusions are based, some of the experiments described by Dr. Bühler are open to objection in themselves. To test a child's social responses and body control at the age of 6 months by making an “angry expression” at it to see if it will react, or by covering its head with a diaper to see if it will remove it, are measures which one would expect to produce not normal but rather fear reactions. There are other features of the book which detract from its value as a serious contribution to the study of child psychology.

Dr. Susan Isaacs's pamphlet[2] belongs to an entirely different category. In it she sets out clearly the broad lines of child development, laying stress on the number of aspects from which it needs to be studied if satisfactory conclusions are to be drawn. While insisting on the importance of the biological background, she claims with justice that any attempt to understand the development of the human child in terms of crude biological returns which overlook his early social relations is quite misleading. Dr. Isaacs's little book should be of value not only to the child psychologist but also to teachers and other educational workers. An interesting feature is her reference to the importance of affective influences in deflecting the whole course of intellectual development and the possibility of psychotic mechanisms producing the appearance of mental defect. Of especial value, too, is the exposition of the stages of maturation of intelligence and the phases of development at which children learn most easily things intellectual and practical. The psychologist will find useful the summary of the methods by which Dr. Isaacs considers psychological data can best be collected: observation, incidental and experimental; experiment, including direct measurement of simple functions and intelligence tests; developmental schedules of age-groups; and psycho-analysis of children. Throughout, the point of view is objective. The pamphlet is intended as a basis of study; it is accompanied by a useful little bibliography and contains unbiased accounts of a wide variety of methods. In the more detailed description of normal and abnormal traits which follows, a brief description of each is given, with the ages at which it most commonly occurs. All this is very suggestive and is allowed to remain so, no attempt being made to regard hypotheses as scientifically tested facts or to base statistics on a small number of cases. The pamphlet concludes with a plea for skilled and sympathetic workers in education and psychology.

Doctors, Chemists, and Population.—The *Pharmaceutical Journal* of Sept. 7th has taken the trouble to work out the proportion of pharmacists and doctors to population in this country. The years chosen are those of the decennial census and the area chosen is not quite the same in the two groups, being Great Britain for the pharmacists and the British Isles for the doctors.

Year.	Pharmacist.	Doctor.
1911	2495	1109
1921	2307	1038
1931	2053	881

Hygienic Caps for Milk Bottles.—The metal cap now being used by United Dairies Ltd. for its milk bottles completely covers the pouring edge of the bottle. In the old type of bottle sealed with a pasteboard disc it was possible for dirt to collect on the disc and on the pouring edge of the bottle. The new cap eliminates this risk, and has the further advantage that it can be replaced as a cover after the bottle has been opened.

The "Annual Review of Biochemistry," mentioned on p. 617 of our last issue, can be obtained from Messrs. H. K. Lewis and Co., Ltd., for 22*s.* 6*d.*

Appointments

Allen, Geoffrey, M.B., has been appointed Hon. Pathologist to the South-Eastern Hospital for Children, London.

Bannerman, R. G., M.D. Edin., Non-resident Pathologist to the Peterborough and District Memorial Hospital.

Dunn, B. Venn, M.D., F.R.C.S. Edin., Hon. Surgeon in charge of Out-patients to the Torbay Hospital, Torquay.

Forbes, Jean, M.B., Junior Resident Medical Officer at the Manchester Babies' Hospital.

Gross, D. M. B., M.D. Leeds, D.P.H., Assistant Medical Officer of Health, Ilford.

Weir, J. H., M.D. Durh., B. Hy., D.P.H., Assistant Medical Officer of Health, Ilford.

Wilson, W. Etherington, F.R.C.S. Eng., Hon. Surgeon to the Torbay Hospital, Torquay.

Wright, A. B. B., M.B. Glasg., Senior Resident Medical Officer at the Manchester Babies' Hospital.

Vacancies

For further information refer to the advertisement columns

Aberdeen Royal Hospital for Sick Children.—Hon. Asst. Surgeon to Ear, Nose, and Throat Dept.

Aberdeen Royal Infirmary.—Hon. Jun. Asst. Surgeon to Ear, Nose, and Throat Dept.

Altrincham General Hospital.—Sen. and Jun. H.S.'s. £150 and £120 respectively.

Barbados General Hospital.—Jun. Res. Surgeon. £325.

Birmingham City.—Asst. M.O. £550.

Birmingham, West Heath Sanatorium.—Res. Asst. M.O. At rate of £250.

Birmingham and Midland Eye Hospital.—H.S. At rate of £130.

Bolton Royal Infirmary.—H.S. £125.

Bradford Royal Eye and Ear Hospital.—H.S. £160.

Brighton, Royal Sussex County Hospital.—H.S. £150.

Central Middlesex County Hospital.—Med. Supt. £1300.

Chelmsford and Essex Hospital.—H.P. and H.S. Each at rate of £150.

Chester County Mental Hospital.—Jun. Asst. M.O. £350.

Coventry and Warwickshire Hospital.—Res. H.S. Also Cas. O. Each £125.

Derbyshire County Sanatorium.—Jun. Res. Asst. M.O. £350.

Eastbourne, Princess Alice Memorial Hospital.—Res. £150.

Middlesbrough, North Ormesby Hospital.—Hon. Orthop Surgeon.

Middlesbrough, North Riding Infirmary.—Third H.S. £125.

Nelson Hospital, Merton, S.W.—Res. H.S. At rate of

New Zealand, University of Otago and Dunedin Hospital. Sen. Res. M.O. £500.

North Riding of Yorkshire County Council, &c.—Two M.O.H. Each £800.

Norwich, Jenny Lind Hospital for Children.—Res. M.O.

Nottingham General Dispensary, Gregory Boulevard Branch. Res. Surgeon. £250.

Nottingham General Hospital.—H.S. for Ear, Nose, and Dept. At rate of £150.

Nottingham Hospital for Women.—H.S. At rate of £150.

Nottingham and Midland Eye Infirmary.—Hon. Asst.

Oldham Royal Infirmary.—Cas. O. and H.P. At rate of £175.

Paddington Green Children's Hospital, W.—H.P. and Each £150.

Queen Mary's Hospital for the East End, E.—Asst. £400.

Queen's Hospital for Children, Hackney-road, E.—H.P. Cas. O. Each at rate of £100. Also Asst. Physician.

Richmond Royal Hospital.—Jun. H.S. At rate of £100.

Rochdale County Borough.—Jun. Res. M.O. for Birch Hospital. At rate of £225.

Royal Eye Hospital, Med. School, St. George's-circus, S.E. Research Scholarship. £100.

Royal Free Hospital, Gray's Inn-road, W.C.—Res. Reg. £100. Also Res. Cas. O. At rate of £150.

Royal Masonic Hospital, Ravenscourt Park, W.—Res. Surg. At rate of £250.

Royal National Orthopædic Hospital, Great Portland-st., W. Two Registrars Each £105.

St. Mary's Hospital, W.—Surg. Reg. £200. Also Reg. and Jun. Clin. Asst. for X Ray Dept. Each £50.

St. Mary's Hospital for Women and Children, Plaistow, E. Resident and Asst. Res. M.O.'s. At rate of £175 £120 respectively.

Samaritan Free Hospital for Women, Marylebone-road, N.W. H.S. At rate of £100.

Sheffield, Jessop Hospital for Women.—Two H.S.'s. Each rate of £100. Also Hon. Surgeon.

Sheffield Royal Infirmary.—Clin. Asst. for Dept. £300.

Southend Municipal Hospital.—Two Asst. M.O.'s. Each

Southend-on-Sea General Hospital.—Pathologist. £600. £100. Also Hon. Visiting General Physician and

Swansea General and Eye Hospital.—H.P. Also H.S. at rate of £150.

Torquay, Torbay Hospital.—H.S. £175.

Wigan, Royal Albert Edward Infirmary, &c.—H.S. At of £150.

Durham County Hospital.—This institution, which almost all the miners contribute, is in need considerable extension. Many more serious cases for admission than can be accommodated. The patients' department is also badly overcrowded. year the expenditure of the hospital exceeded its by over £2000.

ADDRESSES AND ORIGINAL ARTICLES

THE NEUROTROPIC VIRUS DISEASES*

BY E. WESTON HURST, M.D., D.Sc. Birm.,
M.R.C.P. Lond.

MEMBER OF THE RESEARCH STAFF, LISTER INSTITUTE, LONDON; READER IN EXPERIMENTAL PATHOLOGY IN THE UNIVERSITY OF LONDON

I

THOUGH Pasteur in his work on rabies discovered the first perfectly typical neurotropic virus as long ago as 1884, and poliomyelitis was shown to be due to a neurotropic virus in 1909, it is of recent years that our knowledge of the subject under consideration has grown by leaps and bounds; to-day neurotropic viruses are being found to play an ætiological rôle in an increasing number of nervous diseases. The world-wide epidemic of encephalitis lethargica at the end of the last European war was due almost certainly to the action of a virus; though conclusive experimental proof has never been forthcoming—possibly because the disease is transmissible to only one animal, man—all the indications point in this direction. Herpes zoster again is probably excited by a virus. Poliomyelitis is transmissible experimentally to only one group of animals other than man—viz., the monkeys and apes—and among these the New World monkeys are insusceptible; were this virus only a little more selective in its pathogenic activities, our knowledge of the causation of infantile paralysis would be exactly comparable with that of encephalitis lethargica and herpes zoster.

Of late many new neurotropic viruses affecting man and animals have been isolated, and it is quite clear that the discovery of others awaits only the application of the experimental method to cases of hitherto obscure nervous illness. For instance, in 1932 a research worker in New York was bitten slightly by an apparently healthy monkey. A vesicular lesion, accompanied by some lymphangitis, appeared at the site of trauma. Thirteen days later he developed an ascending myelitis, to which he succumbed on the 18th day; from the brain and cord a new neurotropic virus was obtained.[1] In 1933 an outbreak of encephalitis in St. Louis and Kansas City, Missouri, yielded yet another neurotropic virus.[2] In short, the subject of neurotropic viruses is to-day one of the actively advancing wavelets on the tide of medical science.

The Lesions and Their Distribution

Clinically, the activity of these viruses finds expression in symptoms of encephalitis or myelitis, according as the brunt of the attack is borne by a higher or lower level of the nervous system. In the great majority of cases, however, pathological examination reveals participation of all parts of the central nervous system, so that the term encephalomyelitis would seem a more appropriate one. For example, in poliomyelitis, in which commonly the chief symptoms are those of affection of the anterior-horn cells of the spinal cord, there are almost always to be found at autopsy slighter pathological changes in higher regions such as the brain-stem, basal ganglia, and motor cortex, as well as in the spinal ganglia and peripheral nerves. Recent observers suggest that such lesions may have an important influence on the symptomatology in the preparalytic stages of the disease, though later they are completely overshadowed by the destruction of lower motor neurons.

From the multiplicity of known neurotropic viruses it follows that encephalitis or encephalomyelitis is not one malady; in addition to the toxic and bacterial causes of brain and cord disease, there are many viruses capable of attacking the nervous system, and of producing a more or less characteristic clinical syndrome depending on whether they have largely a selective action on a particular region or are fairly diffuse in their activities. And these various forms of virus encephalomyelitis bear no closer relation one to another than does small-pox to measles.

The clinical features of the various maladies and the serious problem of therapy can be considered rationally only in the light of modern researches in pathology and pathogenesis. Our conception of the importance of the various histological phenomena has altered radically of recent years. We believe to-day that the perivascular infiltration and meningitis so prominent in human cases, in which examination must necessarily be deferred until a late stage of the disease, represent in many cases merely the reaction of these tissues to damage to the essential nervous structures. The great majority of neurotropic viruses directly attack and destroy the nerve-cells, whatever effect they may have on the vessels and meninges. In the earliest stages of many diseases in animals, the nerve-cells are already severely damaged before inflammatory signs make their appearance. In the later stages, inflammatory œdema and exudate may play a part in hindering the nutrition of the already affected neurons, and thus decrease their chances of recovery. But in contradiction to the classical accounts of, say, poliomyelitis, which picture the morbid process as beginning in the meninges and spreading thence along the vessels to attack the anterior-horn nerve-cells, I must stress the primary and severe involvement of the neurons. From the theoretical point of view we might expect this, for the viruses are eminently cytotropic organisms parasitising and growing in cells, and the very fact that some are strictly neurotropic indicates their lack of affinity for cells other than the neurons. From the practical standpoint recognition of this fact is fundamental, for nerve-cells do not multiply in extra-uterine life, and a cell once destroyed can never be replaced; the most that can be hoped is that other similar cells may assume its function.

The lesions due to neurotropic viruses are, then, more marked in the grey than the white matter of the brain and spinal cord. The nerve-cells undergo various kinds of degeneration. With viruses of low virulence the changes are probably not irreversible, and recovery of many of the neurons may follow. With viruses of extreme virulence the nerve-cells suffer acute necrosis, and are later engulfed and removed by phagocytic cells in the process of neuronophagia. If in such a case death does not result from involvement of the vital centres, or from secondary pneumonia or urinary sepsis, the patient is left with a loss which no drugs or mechanical treatment can do more than palliate. Coincidentally with, or immediately following the nerve-cell degeneration, inflammatory exudate appears in the tissues, perivascular sheaths and meninges, and may in subacute conditions attain such proportions that in the past it has been accepted as the primary lesion. A point worthy of emphasis is that these neurotropic viruses are not responsible for direct damage to the myelin sheaths; when nerve-cells are destroyed the usual myelin degeneration of Wallerian type ensues in the corresponding nerves and tracts, but a primary attack on the myelin is characteristic of quite another type of encephalitis to which reference will be made later.

---

* Abbreviated from the William Withering lectures in the University of Birmingham, 1935. Lect. II. will appear next week.

Paths of Infection

Concerning the path by which these viruses reach the nerve-cells I shall have to confine my remarks to a few dogmatic statements. Poliomyelitis and rabies viruses are almost never found in either blood or cerebro-spinal fluid; the few positive results recorded have been obtained during the period of the declared disease, and hence are of no importance in indicating by which route the virus travelled during the incubation period. Other viruses, for instance that of pseudorabies, do occur in the blood, but it can be proved that they do not reach the nervous system by its agency.[3] On the other hand, it is known that poliomyelitis and rabies viruses do not reach the brain or cord if the nerves supplying the part inoculated are sectioned, showing that the virus travels by some anatomical component of the nerve trunk. After inoculation of poliomyelitis virus into the *left* sciatic nerve, virus and lesions first appear in the lumbar cord and next in the leg area of the *right* motor cortex.[4] Remembering that the pyramidal tract decussates in the medulla, it seems that the structure transmitting the virus in this case must be the nerve fibre itself. Further evidence has been furnished by transection of the cord and subsequent intracranial inoculation of virus, when virus and lesions are found only in that part of the cord above the point of section, though the segments below are still bathed with cerebro-spinal fluid and their blood-supply is intact.[5]

How then does the neurotropic virus reach the central nervous system in the case of natural infection? In rabies, of course, the virus is introduced by the bite of a rabid animal. In pseudorabies the virus probably enters in a similar way through a crack or abrasion in the skin or mucous membranes. In both cases the virus then infects the local nerve-endings and passes up the corresponding peripheral nerve to the cord. Probably, however, the usual route of entry of the neurotropic viruses is by the nose. The intranasal method of infection, by instilling drops of infective material into the nares of animals, is one attended experimentally by a considerable measure of success, even though it avoids all trauma which might be expected to facilitate the establishment of the virus. In the case of poliomyelitis it has proved possible by rather unusual experimental measures to infect monkeys by the gastro-intestinal route, but there is no proof that this is the route of invasion under natural circumstances. A few observers believe that the greater frequency of paralysis in the legs than in the arms or bulbar muscles is indicative of intestinal infection via the splanchnic nerves, but against this view must be set the observation that whatever the route of infection the legs are very frequently first and most affected. No, the evidence available is strongly in favour of an entry under natural conditions by the nose, and perhaps in cases of the bulbar form of the disease by the tonsils or nasopharynx. For a virus which has affinity only for nervous tissue, the nose constitutes a peculiarly convenient portal of entry. The terminal fibrils of the olfactory nerve are directly exposed on the surface of the olfactory mucosa, and after a short extracranial course pass through the cribriform plate to deliver the virus directly into the susceptible nervous system. The implications of these findings are far-reaching. If the results of animal experimentation can be applied to human pathology, poliomyelitis is from the first a primary disease of the nerve-cell, and there is no systemic or blood phase of infection during which liberal treatment of the patient with antiserum can prevent the virus from reaching the nervous system.

The foregoing account has not taken into consideration a small group of viruses which behave in quite a different manner and which I should mention for the sake of completeness. The only examples we know at present are the viruses of louping-ill, equine *encephalomyelitis*, and yellow fever. They are all transmitted by the bite of a blood-sucking insect and they all circulate in the blood: the nervous infection is intimately connected in a manner yet unexplained with their presence in the blood stream, and they do not ascend by the peripheral nerves. In the case of the unmodified yellow fever virus the neurotropic affinities are masked by the stronger viscerotropic action, but passage of the virus from brain to brain in mice is effective in revealing its neurotropic potentialities.

Clinical Differences between Virus Diseases

Now neurological symptoms and signs are determined in great part by the particular nervous structures involved, and by the tempo of the destructive process. Morbid processes of quite different nature may give rise to much the same symptoms. Localisation of a focal lesion depends solely on an accurate knowledge of anatomy, while diagnosis of the nature of the lesion is a much more difficult proposition. Since we have in so many cases a clinical syndrome characteristic of a particular virus disease, it follows that the symptomatology depends on one or two factors; either it is influenced by the portal of entry of the virus, and this must vary in the different infections, or the virus has a special predilection for certain areas of the brain or cord. It is possible to choose examples illustrating the operation of either of these factors. Intracerebral inoculation in the rabbit of the recently isolated B virus[1] leads to manifestations of encephalitis—hyperexcitability, convulsions, and speedy death. If, however, the virus is inoculated intramuscularly or intracutaneously, the invasion of the cord by way of the corresponding peripheral nerve sets up an ascending myelitis, which only after several days involves the vital centres of the medulla and thus in all respects copies the condition in man. Here the portal of entry of the virus is all-important in determining the symptomatology; presumably this virus has equal affinity for all parts of the central nervous system, and the clinical course depends on which level is first attacked. On the other hand, whatever their route of entry, certain viruses have a remarkably selective action on certain types of nerve-cell. Thus the main attack of poliomyelitis virus is on the anterior-horn cells of the spinal cord, that of louping-ill in the monkey on the Purkinje cells of the cerebellum, that of pseudorabies in the monkey on certain parts of the cortex near the temporal pole and the calloso-marginal fissure. The site of election of Negri bodies in the cornu Ammonis in rabies possibly represents higher resistance of a certain type of nerve-cell to the virus. It must not be concluded that in the cases quoted no damage occurs elsewhere; indeed I have already emphasised the diffuse distribution of the lesions due to almost all neurotropic viruses. But while in, shall we say, louping-ill, practically every Purkinje cell of the cerebellum is usually destroyed, in the cortex, basal ganglia, brain-stem, and cord only a small and variable proportion of neurons suffer the most severe changes, with the result that the symptoms are dominantly cerebellar. In contrast we may consider the protean symptoms of the acute stages of encephalitis lethargica to be due to the variable distribution of the most severe lesions, though even here certain symptoms recurred in a considerable percentage of cases.

We are now in a position to consider individually some of the commoner neurotropic virus diseases, and perhaps first of all poliomyelitis claims attention.

Poliomyelitis

Many practitioners still think of poliomyelitis as a disease characterised chiefly by a more or less extensive, flaccid paralysis of sudden onset, often persisting as a permanent disability. But this is not the complete picture of the malady as we know it to-day. Poliomyelitis is a disease probably affecting a very large proportion of the community—at least of the urban community; it is only occasional cases, estimated by some at less than 1 per cent. of the total infected, which develop paralysis and are diagnosed as such. Where investigations have been made it has commonly been found that 50–80 per cent. of the adolescent and adult population carry neutralising antibodies in the serum, and with very few dissentients bacteriologists believe that this is certain evidence of previous infection. If this view is correct, we must assume that in these cases symptoms of infection have been so indefinite that, if attracting attention at all, they have been attributed to a slight chill or other minor ailment and their significance missed. We might be less inclined to believe this were there not cases of intermediate severity, the so-called abortive cases, in which symptoms, while sufficiently definite to attract attention, do not progress to paralysis.

In America, diagnosis of these abortive cases is becoming increasingly frequent on the basis of a suspicious symptomatology confirmed by cerebro-spinal fluid examination. In this country, unfortunately, diagnosis is commonly not made until the child has been paralysed for 24–48 hours. This is partly due, of course, to the greater relative frequency of sporadic cases, but it is also in part attributable to the fact that the general practitioner has not been taught to recognise the initial symptoms as those of poliomyelitis. In the period when the disease was believed to be due to a systemic infection only later localising in the nervous system, the tendency was to dismiss the early symtoms as those common to all febrile disturbances. Now that it appears highly probable that from the first entry of virus by the nose poliomyelitis is a nerve-cell disease, observers are realising that the initial symptoms must be indicative of the march of the virus from nucleus to nucleus on its way to the cord.[6]

In the *first phase* of poliomyelitis it is not so much the individual symptoms that count as the general impression received by an experienced observer. As an American authority says:—

> ". . . there seems to be little doubt in the minds of those who have seen much of the earliest hours of the disease that a very definite and characteristic clinical picture presents itself. But it is difficult by descriptive method to transfer an adequate impression of the subtle and striking difference between the onset hours of infantile paralysis and those of any other of the acute infectious diseases of childhood. To say that the temperature is elevated, often as high as 103° or 104°, and that the child is flushed and miserable; that vomiting often occurs and that drowsiness supervenes, does not offer sufficiently distinguishing evidence of the special type of infection. Nevertheless, this common symptom complex is shot through with delicate manifestations that are unmistakably specific, but which must still be viewed as clinical impressions—those helpful though indefinite aids in diagnosis.
>
> "Now when infantile paralysis becomes epidemic in a locality which has been previously free from its presence, the physicians in that territory soon appreciate this difference from the usual illnesses of children—there is a look of mingled apprehension and resentfulness quite unlike the alert, bright, and shining eye of other fevers. The psychic change responsible for this look finds further expression in a characteristically annoyed shrugging of the shoulder which occurs when the child is touched or simply spoken to. Indeed, there is frequently a snarling whine of resentment which is synchronous with this gesture of discontent. . . . (In) cases of overwhelming infection . . . there are other striking phenomena. The child is restless, breathes rapidly, and seems to be busily and actively resisting some incomprehensible disturbance of its usual comfort. In these instances, the irritability and resentful manner are not marked, but the whole organism seems to be composed of tensely drawn wires —a universal overstimulation. This pressor state of the nervous system is so marked that a sort of impulsive ataxic tremor is present in every motion, especially when that motion has intent. . . . Usually a few cases are met with whose profound stupor masks all other signs and symptoms. . . ."

Among the manifestations of specific nature here mentioned we may note especially (1) disturbance of sleep rhythm—sleepiness by day and restlessness by night as occurs in a more pronounced degree in some cases of encephalitis lethargica; (2) general hyperæsthesia to every touch and passive motion whatever their situation; (3) disturbances of the vegetative system—sweating, flushing, disturbed intestinal peristalsis, tachycardia, and so on. It has been suggested[6] that almost all of the symptoms at this stage can be referred to lesions in the thalamus and hypothalamic region, and we know that after intranasal inoculation in the monkey these are among the first centres infected from the olfactory bulbs.

In the *second phase* of the disease, still in the absence of paralysis, the foregoing symptoms continue, but new symptoms and signs are now more prominent. These are localised pains and tenderness (rather than general hyperæsthesia), stiff neck, painfulness of the neck and spine to flexion. Ataxia, tremor, and early weakness follow. According to the older theory of pathogenesis, these are signs of meningeal irritation announcing the extension of the systemic infections to the meninges. To-day, knowing that there is no systemic infection and that meningitis is not a feature at this stage of the disease, but that there are lesions in the spinal ganglia and posterior horns of the spinal cord, we accept these symptoms as evidence of the further march of the virus from higher regions to lower, probably largely through the spino-thalamic tract.[6]

The *third phase* of poliomyelitis, that of flaccid paralysis, represents the final onslaught of the virus on the motor cells of the anterior horn, which for some unknown reason are peculiarly susceptible to its action. To diagnose poliomyelitis at this stage is equivalent to shutting the horse's tail in the closing stable door.

The rate at which the disease progresses from one point to another is subject to considerable variation.[6] In some cases it is more than a week from the appearance of the first symptoms before paralysis occurs. In the abortive cases (diagnosed by positive findings in the cerebro-spinal fluid) paralysis never occurs, though there is little difference between the initial symptoms in this group and in that which later becomes paralysed. In many cases there are intervals of interrupted progress—in fact there is in man a conspicuous tendency for the disease to come to a stop temporarily or permanently anywhere in its course. On the other hand, many cases progress very rapidly. Nevertheless, it is rare to find a case in which characteristic alterations of the spinal fluid cannot be detected before the appearance of paralysis, and early diagnosis can almost always be made, provided that knowledge of the early symptoms suggest to him the simple operation of lumbar puncture.

In the text-books are described various forms of poliomyelitis, the bulbar, the cerebral, the cerebellar, &c. The returns of the Registrar-General each year report a certain number of cases, constituting possibly 20 per cent. of the total, and designated polio-encephalitis. What they all are is very difficult to find out. Some, no doubt, are bulbar cases of poliomyelitis, that is, cases in which the motor nuclei of the brain-stem happen to be more affected than those of the cervical and lumbar cord; to label them polio-encephalitis may be technically correct, but is nevertheless confusing as there is no essential difference between them and the usual forms. Levels of the central nervous system above the brain-stem are probably never involved more severely than is necessary to produce the symptoms of the preparalytic stage, and the so-called cerebral and cerebellar forms of the disease are almost certainly due to some other cause; it has never been shown that the virus of poliomyelitis can evoke such syndromes in either man or monkey.

Landry's Paralysis

Another syndrome to which I must now briefly refer is that passing under the name of Landry's paralysis. By definition this is an acute ascending flaccid paralysis with minimal sensory and sphincter disturbance. Most of the cases prove fatal from involvement of the medullary centres. Cases which recover are said to do so completely. Fatal cases show no definite changes in the nervous system, which fact perhaps links the condition to the more severe types of acute toxic neuritis.

Now an identical symptomatology may obtain in at least two neurotropic virus diseases, though sections show in these cases definite and characteristic lesions in the spinal cord. One such disease is poliomyelitis—the more severe cases with weakness beginning in the legs and rapidly ascending to the medulla fulfil all the clinical requirements of Landry's description. The second condition is rabies. In the usual form of this malady the symptoms until a late stage are those of overstimulation rather than of paralysis of the nerve centres. But sometimes in man, and constantly in certain species of animals, paralysis predominates from the start. In most parts of the world human ascending flaccid paralysis due to rabies is far from frequent; in an outbreak in Trinidad, however, in the years 1929–31, all the cases were of this type, and the nature of the infection was never suspected until animal inoculation revealed, not the virus of poliomyelitis which had been under suspicion, but that of rabies.[7] Even then it was not clear whence originated the infection, for the island has as strict a quarantine as does this country, and rabies in dogs is unknown; finally some evidence was accumulated to incriminate the vampire bat, biting the toes of natives sleeping in the open, as the transmitter of the virus.

It seems, therefore, that we can either accept the original and text-book specification of Landry's paralysis, with the proviso that we cannot possibly be sure of the diagnosis until we have histological preparations of the spinal cord, or we must admit that Landry's paralysis is no more than a clinical syndrome common to a number of very different conditions.

Herpes Zoster

We have seen that poliomyelitis virus has an especial affinity for the lower motor neuron, and we may now devote a moment to herpes zoster which attacks the lower sensory neuron. We believe zoster to be a virus disease both on general and epidemiological grounds, and because inclusion bodies have been found in the vesicular skin lesions. We have, however, no final proof of this, partly because zoster is not a fatal disease but chiefly because we have no experimental animal in which to test our theories. Up to the present, transmission with fluid from the vesicles has succeeded only in children who have not suffered previously from zoster or varicella; such children develop either a localised vesicular lesion or occasionally a generalised eruption indistinguishable from that of varicella. In zoster the most marked changes are usually in the spinal ganglia corresponding to the level and side of the eruption, or on occasion in the Gasserian or geniculate ganglia in the case of the rarer distribution of the eruption, but the corresponding nerves and nerve-roots are involved, as are also the posterior horns of the spinal cord. Very rarely the anterior horns are affected and paralysis ensues. There are two groups of cases, that in which no known predisposing cause operates, and that in which the eruption is precipitated by some other pathological condition of the ganglion—syphilitic inflammation, carcinomatous infiltration, trauma, arsenical medication, and so on. Since specific complement-fixation tests are obtained in both groups, if the former is ultimately proved to be due to a virus, we shall have to conclude that the latter is caused by the same virus latent in the patient until activated by the predisposing morbid condition.

Most interesting, however, is the apparent relation of zoster to chicken-pox. Quite often the latter has been reported as occurring, within the usual period of incubation, in a recent contact with a case of zoster, and much less often the reverse has been noted. Zoster and a generalised eruption like that of varicella may occur together in the same patient. With the complement-fixation test cross-immunity between the two infections can be demonstrated.[8] Finally it has proved possible to isolate from the vesicular fluid in zoster and varicella elementary bodies similar to those in vaccinia and small-pox. Pure suspensions of the bodies of either origin are specifically agglutinated by both zoster and varicella convalescent sera.[9] It is clear that the relation between the two infections, suspected now for many years, is a close one.

Encephalitis Lethargica

The next disease demanding consideration is encephalitis lethargica. It first appeared in Europe about 1917, and soon spread to almost all countries. In Japan it occurred together with an entirely different virus encephalitis, which had been recognised previously and has outlasted encephalitis lethargica; the two are there known as the Type A and Type B encephalitis respectively. Many workers were attracted to this new field of investigation, and then the acute disease virtually disappeared.

Again, on general grounds we believe this to be a neurotropic virus infection, but again final proof is not forthcoming. Various claims have been made that the virus has been discovered, but in most instances the organisms isolated appear to have been strains of the virus of herpes febrilis. Since this virus has been obtained from the cerebro-spinal fluid of a case of neurosyphilis, and other evidence speaks against its ætiological rôle in this connexion, only a mere handful of observers believe that it is the cause of encephalitis lethargica. Inclusions of the type usually associated with virus infections have been described but rarely, and on these occasions the diagnosis has not been beyond doubt. Our present interest in the condition is thus largely clinical.

Encephalitis lethargica began as a hyperacute malady characterised by headache, vertigo, delirium, and convulsions. The average onset then became more gradual, and lethargy occupied a prominent place in the symptomatology. Coma occurred in the terminal stages. Often restlessness at night alternated with sleepiness by day—a symptom which we have already seen obtaining in slighter degree in the preparalytic stages of poliomyelitis. Occasionally the reverse disturbance of sleep, insomnia, prevailed. Ophthalmoplegias due to damage to the ocular nuclei of the mid-brain were an almost constant feature. Choreiform movements, myoclonic muscular contractions, a parkinsonian facies, and catatonia also occurred in some of the earlier acute cases. Roughly one-third died, one-third recovered, and one-third passed into the chronic stage; in the last group both mild and severe initial cases were represented.

In the chronic disease many of the major features of the acute attack are represented in a modified form.

Extrapyramidal disturbances of motility find their expression in the condition of parkinsonism, probably resulting from injury to the substantia nigra.

Mental symptoms indicating involvement of the highest levels of the central nervous system were in mild cases confined to protracted nervousness, undue lassitude, anxiety, depression, and inability to concentrate. Often, however, especially in children, they were more severe, and constituting a complete reversal of the patient's previous mentality and morality led him into abnormal behaviour which in many cases necessitated institutional treatment.

In the earlier days of the epidemic disorders of sleep often persisted after the acute stages. Lethargy, insomnia, and reversal of sleep rhythm need no further mention. Narcolepsy was an occasional sequel; it also occurs, of course, as an independent disease. In this condition the patient feels an uncontrollable desire for sleep which must be gratified however inconvenient the time or place, and he lapses into slumber during the course of conversation, and passes his destination in tram or bus. The attacks may recur several times daily or only at infrequent intervals, and last usually only a short time; they often come on in circumstances normally conducive to sleep, as after lunch on a warm day.

Possibly allied to these disorders of sleep are peculiar periodic attacks usually involving the musculature of the eyes and jaws, upper trunk and limbs, or the respiratory mechanism. Among the most interesting are the oculogyric crises. The patient may state that with or without warning the eyes "shoot up into the head." As a rule the movement is upwards, but it may be in other directions. The eyes become fixed and cannot be brought back. This may take place twice or thrice a day or only once in several weeks, and may last a few minutes or several hours, during which time the patient is helpless. Not infrequently an attack ends in sleep, and sleep always ends an attack. It may be started by emotional excitement, but sometimes also be inhibited by will or by some external, mental or physical stimulus. Retraction or deviation of the head, restlessness, dizziness, flushing of the face, diplopia, opening of the mouth, all may accompany the attack; sometimes the crises are accompanied by curious psychological phenomena in the nature of compulsive ideas. There is evidence that in this condition the eye muscles are not in spasm as one might think, but at rest; in other words the eyes are in the position to which normally they wander during sleep—a position which varies in different individuals and perhaps in the same individual at different times. In short it seems that the ocular muscles have gone to sleep while the remaining phenomena of sleep are absent. Similarly attacks of lid-closing may represent a dissociation of the phenomena of normal sleep.

Disorders of respiratory rate, usually in the direction of an increase, may be paroxysmal or continuous. Alterations of respiratory rhythm, or breath-holding spells accompanied by choreo-athetoid movements of the limbs and bizarre attitudes, or respiratory tics including yawning, sniffing, spasmodic cough and spitting are also encountered.

Some Other Neurotropic Virus Infections

Of the other neurotropic virus infections, the Australian X disease, though largely a disease of childhood and adolescence, differs from poliomyelitis in that the symptoms are mainly cerebral in nature; paralyses are rare and not persistent. From encephalitis lethargica the diagnosis is made by the infrequency of cranial nerve palsies and the usual complete recovery. The virus, moreover, is definitely pathogenic for monkeys, sheep, and other animals. The fact that some sheep are refractory to infection suggests possibly that this is a disease also, or even primarily, of domestic animals.

The B virus has been responsible for two cases of ascending myelitis, one in a research worker who was bitten by an apparently healthy monkey, the other in a laboratory attendant accustomed to handle these animals. For this reason, and because normal monkeys may show a high titre of neutralising antibodies to this virus in their serum,[1] it appears that the disease is one frequently occurring in the monkey: experimental work shows that the monkey infected in the skin with the virus does not acquire a fatal myelitis but may survive immune. On the other hand, in the rabbit a disease develops exactly similar to that in man, and invariably proceeds to a fatal termination.

Another animal disease potentially capable of affecting man is louping-ill. This malady of sheep is endemic in some areas of Scotland; since the virus was first isolated in 1928 no fewer than four laboratory workers have developed symptoms varying from a mild attack of what was called influenza to a definite encephalitis with headache, vomiting, delirium, tremor, and lethargy, with subsequently neutralising antibodies to the virus in the blood.[10] The possibility of the disease occurring in farm hands in the infected areas should be considered.

The St. Louis outbreak of encephalitis[2] occurred in that town and Kansas City during July to October, 1933, and affected more than a thousand people. In many respects its chief features were those of the Japanese type B encephalitis. For example, it occurred in elderly rather than young subjects, and although the total mortality was in the neighbourhood of 20 per cent., only 5 per cent. of patients under the age of forty succumbed. However, the identity of the two has since been denied. Although certain workers hailed the outbreak as one of encephalitis lethargica, it differed in that a virus pathogenic for mice and monkeys was isolated without difficulty. Mental confusion, aphasia, tremor of the hands, tongue, and lips, and drowsiness seem to have been the commonest symptoms, though vertigo, ataxia of the arms and legs, facial paralysis, and spastic weakness of the limbs are also recorded. Ocular symptoms were rare. Recovery was rapid and complete.

It is perhaps difficult for us to interest ourselves greatly in outbreaks of encephalitis in Japan, Australia, and the Middle West of America; these countries are so remote and there are so many pressing problems nearer to hand. But I feel that we should at least bear them in mind. Not only may their study throw light on what has hitherto been obscure in more familiar infections, but to-morrow may see them epidemic in our own population. Year by year transport becomes more and more rapid, and more and more people travel widely. When the present economic depression is over this tendency will be even more apparent than to-day. Another war may bring into direct contact peoples from opposite ends of the earth. It is within the bounds of possibility that there may result world-wide epidemics of diseases previously confined to one locality, and among these we must not ignore the various types of encephalomyeltis.

THE FORCEPS OPERATION

BY A. JOSEPH WRIGLEY, M.D. Lond., F.R.C.S. Eng.

OBSTETRIC PHYSICIAN IN CHARGE OF OUT-PATIENTS, ST. THOMAS'S HOSPITAL, LONDON

IN an attempt to lessen mortality, damage, and illness resulting from the abuse of the forceps operation obstetric leaders have for many years advocated the decreased use of the instrument. The fact that this advice has required such repetition shows that for the most part the seed has fallen upon stony ground. In those hospitals which are in charge of the expert obstetricians, some control can be and is directed to the incidence of the forceps deliveries. Such institutions indeed take pride in an ever-decreasing forceps rate. But obstetric practice outside hospitals presents altogether another problem. A forceps delivery may be forced upon the doctor in charge by pressure from the patient or her relatives; he may have been engaged to conduct labour with the express purpose of ensuring its expedition; he may himself be pressed for time and quite unable to spend several hours watching the fœtus appear and disappear; or his efforts may be directed solely towards relieving the patient of what he considers to be unnecessary suffering. In addition to these possible factors, the control of a patient in her own home is a very different matter from her control as an inmate of a large hospital. For all these reasons I contend that advice directed against the use of the forceps is unlikely to be acceptable because it is not really practical.

The following figures were obtained from one of the leading maternity homes in London and the patients, for the most part, were under the care of obstetric specialists who are teachers of this subject. Delivery was completed by the forceps operation in 203 of the last consecutive 300 cases (primiparæ). The maternal morbidity was low, under 2 per cent., the maternal mortality nil, and the infant mortality under 3 per cent. In the great majority of cases the fœtal head was resting on the pelvic floor. It is thus likely to be more profitable to find some way of reducing the risks associated with the application of forceps than to attempt to stop their use. I hope to show that the substitution of a short light forceps for the axis-traction design will meet the needs of the doctor and will enable him to shorten labour without danger to mother or child. In order to appreciate the reasons why the axis-traction forceps should be superseded by a more suitable instrument for the delivery of a head low in the pelvis it is necessary to recall briefly the history and evolution of the obstetric forceps.

About the beginning of the seventeenth century the prototype of the obstetric forceps was devised by the Chamberlen family. It is sufficient to note that for the first 150 years of its existence the instrument was of the short straight variety. The lock was then added, as also was a short shank, whereby the radius of the cephalic curve was lessened and the blade more closely fitted the fœtal skull. In the middle of the eighteenth century Levret and Smellie independently altered the existing type by lengthening of the shank and adding the pelvic curve. After another century Tarnier introduced the principle of axis traction.

During the last eighty years there has been no change and the modern instrument used in practice and in the teaching schools is the long curved forceps with some axis-traction modification.

This evolution of the obstetric forceps was consequent upon the use to which the instrument was put. Primarily the forceps was used to aid delivery of the fœtal head; for obvious reasons the instrument could only be applied to a head low in the pelvis. In the attempt to adapt the instrument to assist the delivery of a fœtal head obstructed in the mid-pelvis the forceps was lengthened. The tractive power was greatly increased by the addition of the English lock by Smellie. The blades were applied more correctly to the fœtal skull and the attitude of flexion was less disturbed by the addition of the pelvic curve. The final refinement was the application of the various axis-traction modifications. These are ingenious and for the main part mechanically sound. With their aid an immensely greater tractive effort may be exerted.

Disadvantages of the Axis-traction Forceps

There is to-day little need for the continued use of this bulky, powerful, and ingenious instrument. The conditions that may necessitate a forcible extraction of the fœtus are cases of disproportion between the pelvis and the fœtal head as a result of contraction of the former or malposition of the latter. Occasionally the delivery of the fœtal head from the mid-pelvis may be considered advisable owing to the appearance of signs thought to be indicative of fœtal distress. It is my considered opinion that in such cases a forcible and rapid delivery often prejudices the survival of the baby.

Before the late war preventive medicine began to establish a hold on obstetrics, and from 1919 onwards what we know as antenatal supervision has developed rapidly. One of the aims of antenatal work is to discover those cases in which obstruction may occur in labour because of a misfit between the head of the child and the pelvis of the mother. It is not necessary here to discuss the many methods used to deal with the problem of dys-tocia, or to criticise the success or failure thereof. One result, however, is apparent. Whenever any serious attempt at antenatal supervision has been made the major degrees of disproportion have been foreseen. The detection of the abnormally small pelvis or large baby is not now left until a condition of obstruction has developed after some hours in the second stage of labour, but the presence of disproportion is discovered during the preg-nancy. The fœtal head that is not engaged in the pelvis in the latter weeks of pregnancy is regarded with grave suspicion and every effort is made to detect a possible misfit. In consequence, even in the obstetric hospitals to which such emergencies are sent, it is unusual to see ses in which completion of the labour necessitates struction of the child or the high forceps operation. ould a case of this nature occur it almost invariably found that the patient has had no antenatal examination.

It has been pointed out above that the long curved rceps as used to-day was conceived, designed, and nstructed to deal with the case of the woman whose regnancy had had no supervision and in whom bstructed labour had occurred, the fœtal head having iled to descend in the pelvis. There is abundant roof, clinical and statistical, that to-day the high rceps operation for minor disproportion is seen ut rarely, and, in theory, it should never be required hen the patient has had adequate antenatal care. elay in labour may occur with the head in the midelvis or at the pelvic brim as a result of incomplete tation or flexion or because of the posterior position f the occiput. Miller and Stacey, in an analysis f the causes of the "failed forceps" operation, nowed that the occipito-posterior position is a most nportant cause for the failure to complete delivery.

When delay in labour occurs and the fœtal head is nywhere but on the pelvic floor there is no call for he use of an instrument lengthy enough to reach and rasp it. Such delay indicates, rather, the anæsthetisation of the patient and a thorough examination o ascertain the cause. Too often this is not done. he forceps are applied, a silent appeal is sent out o the goddess of luck, and a good deal of force xerted. This usually results in the "failed forceps" ase to which reference is made below.

Certainly in theory, and almost as certainly in ractice, there is to-day far less indication for the igh forceps operation and therefore for the use f the long curved instrument.

That the use of the long curved forceps is fraught vith potential dangers to mother and child is well nown, so much so that most writers of text-books onsider it necessary to devote a special section to the langers of the forceps delivery. The student is varned that the lower segment and the cervix may be torn if the head of the child is forcibly pulled through an insufficiently dilated cervix, that the vagina and vulva may be injured, and that the bladder even may be torn. Post-partum hæmorrhage may follow too rapid delivery, and uterine sepsis is more likely to supervene in such cases. The skull of the child may be fractured or its scalp torn, the face of the child may be paralysed or its eye may be injured; meningeal or cerebral hæmorrhage in the child may occur.

This frightful list is no exaggeration. It has, in fact, been reproduced from a well-known standard text-book, and most of the calamities prophesied may in fact be encountered by one with only a small experience of obstetrics. But the whole story of the dangers attendant on the use of the forceps has by no means been told, notably the great danger to the mother of the so-called failed forceps case. Such cases occur so frequently and are accompanied by so extensive a maternal mortality and morbidity as to cause grave concern, and the subject comes up for discussion regularly at meetings of the obstetric societies throughout the country.

It has been shown repeatedly that failure to complete the delivery with the forceps often is not due to a mechanical obstruction. In only a minority of cases is [illegible] "delay" in labour due to the fact that the baby's head is too big for the pelvis; thus, lack of adequate antenatal supervision is not responsible in any way for the failure.

Stacey,[1] in a review of 154 of such cases, found that in no fewer than 100, or 66 per cent., the forceps were applied when the cervix was not adequately dilated to deliver the child. In 47 of these cases there was no possible cause, other than the incompletely dilated cervix, to account for the failure to deliver. In 3 per cent. only of the series was failure to complete the delivery due to disproportion. Miller,[2] in a study of 558 cases, has demonstrated precisely the same causes for the failure. In this series the application of the instrument while the woman was in the first stage of labour, or prematurely to a head in the occipito-posterior position, accounted for 3 out of every 4 cases where failure to deliver had occurred. There was a maternal mortality of 10 per cent. in Miller's series of cases. Stacey gives a most comprehensive review of the end-results of this disastrous complication. The maternal mortality was 14 per cent. and the maternal morbidity (B.M.A. standard) 25 per cent. Only 48 per cent. of the infants survived. A follow up of the patients who recovered showed that over half the women suffered from damage to the perineum, vagina, or cervix, which in a few amounted to the grossest examples of trauma involving the lower uterine segment, bladder, or rectum, and resulting in vesico-vaginal and recto-vaginal fistulæ.

I have directed attention to failure to deliver after the application of the forceps because its consequences are so serious. The authors of text-books have, almost without exception, omitted to insert sufficiently grave warnings on this subject, other than that the instrument should not be applied unless the cervix is fully dilated and taken up. The increased risk to the child in the high or medium forceps operation requires no emphasis. In many of these cases the instrument is applied to a fœtal head not fully flexed or to one lying transversely, obliquely, or with the occiput posterior in the pelvis. Crawford's[3] remark that the same doctor who handles a new-born infant with the gentlest care thinks nothing of applying powerful compression to the fœtal head is worthy of serious consideration.

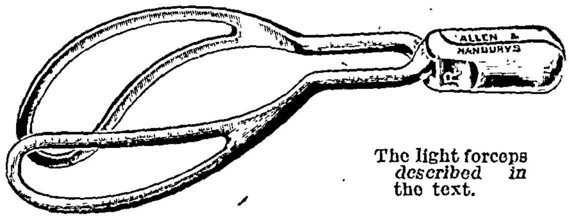
No further emphasis need be laid on the danger both to mother and child that may attend the use of the long curved forceps with axis-traction modification. To-day there should but rarely be the necessity to resort to any but the low forceps operation, which consists in the lifting of the fœtal head past the perineum. The question may next be asked why it is that throughout the country the medical student continues to be taught the use of a heavy and powerful instrument so constructed that (1) it can be applied to an undescended fœtal head, (2) it can be used when the os is not fully dilated, when its misuse is attended by the risk of grave danger to both mother and child, and when the circumstances for which it was designed no longer exist in theory and are but rarely seen in practice? The misuse of this instrument is variously described as being the result of ignorance or apathy on the part of the practitioners, or the deficient teaching of practical obstetrics to the medical student. Thus the Scottish Departmental Committee in their interim report state[4] that: "in nearly one-third of the cases classed as errors of judgment on the part of the doctor, the mistake was premature application of the forceps."

REASONS FOR ITS CONTINUED POPULARITY

The explanation for the continued popularity of the long curved forceps is probably to be found in the combination of a number of circumstances. First, the instrument has the weight of tradition behind it, and though it has its dangers, is used and has been used times without number to put an end to pain and suffering. Secondly, it is only in a small percentage of cases that its use is accompanied by damage to the mother and child. Thirdly, in the teaching schools its use is to some extent regulated and restricted. Teachers have largely themselves to blame for the students' lack of appreciation of the potential dangers of the mid- or high-forceps operation. This operation is almost universally relegated to the house-officer, or at the best the obstetric registrar may be asked to give his aid. It is unconvincing, to say the least of it, to thunder or bewail at the probable dangers attendant upon a certain procedure when its execution consistently is left in the hands of a junior. The solution of the difficulty does not lie in the making of rules which shall regulate the circumstances under which the forceps may be used. Such rules have been formulated, repeated and emphasised. They are for the most part unavailing and Miller [2] sums up the situation very well in saying that "to insist that the forceps should not be applied unless on strict obstetrical indications may be a council of perfection." The solution is that the medical student should never see the long curved instrument used for routine forceps delivery. The appearance of this instrument should be respected and whenever possible accompanied by a visit of the obstetric physician to the labour ward.

A Short Light Forceps for Delivery of the Low Fœtal Head

What is needed nowadays is an instrument that can complete the delivery of a fœtal head that is low in the pelvis. This instrument should be designed for the purpose and its design should be such that it cannot be applied to the head that is high in the pelvis or through an undilated os, and that its application cannot be followed by the employment of tremendous tractive efforts. Two hundred years ago William Smellie [5] wrote "to free myself from the temptation of using too great force, I have always used and recommended the forceps so short in the handles that they cannot be used with such violence as will endanger the woman's life." Miles Phillips [6] comments on this teaching and writes: "I tell my students that the long curved forceps might well be kept at the Town Hall, and be only available on a magistrate's order." This is an excellent suggestion in more ways than one for by the time the innumerable application forms had been duly filled in, signed and countersigned, and the instrument procured, the baby would mostly have been born.



The light forceps described in the text.

In William Smellie's day there was no antenatal supervision and in consequence it must be supposed there was a correspondingly greater number of cases in which the use of the long curved forceps was indicated. Yet even he advocates an instrument with short handles which cannot be used with great force. The universal adoption, especially in the teaching schools, of a short light forceps is greatly to be desired. Some few years ago I discarded the long curved instrument and began to use Simpson's short straight forceps. The instrument had the disadvantage that an incorrect application to the fœtal head was probable. The tips of the blades were apt to grip, bruise, and mark the skin of the baby's head over the supra-orbital ridges. The usual pelvic curve was therefore added to the blades. The instrument I now use (see Figure) weighs less than 10 oz., that is to say, it is about one-quarter the weight of its heavier predecessor. The lightness of the instrument gives the accoucheur an added sense of confidence in that he can appreciate exactly the passage of each blade during its application.

A SERIES OF DELIVERIES BY LIGHT FORCEPS

An analysis of the last 58 consecutive deliveries of primiparous women in my practice shows the following figures.

In all these 58 cases the fœtus presented by the vertex and when the forceps were applied the light instrument only was used. In 23 women delivery was unaided. In 32 women the head was lifted through the pelvic floor with the forceps. In 3 cases manual rotation of a fœtal head in the persistent *occipito-posterior position* was required. The fœtus was delivered easily with the light forceps in 2 of these women. The fœtal head did not sink down into the pelvic cavity after rotation in the remaining case and the long forceps were applied.

From this series it may be argued that it was unnecessary to lift the fœtal head through the pelvic floor in the 32 cases in which this was done, and that these women, if they had been left alone, would have delivered themselves successfully. Probably this would have occurred eventually. But the duty of the attendant is to alleviate pain in so far as it is possible to do so without prejudicing the life or well-being of the mother or child. That has been a legitimate excuse for numberless forceps deliveries in the past. I hold the view that, with efficient ante-natal supervision, by far the most important cause of delay in labour occurs when the fœtal head reaches the pelvic floor and that the very low forceps operation required to effect delivery at this stage is unaccompanied by harm to the mother or child. In the series of cases cited above all the babies were delivered alive and well, with one exception in which there was no bone formation in the vault of the fœtal skull. There was no maternal morbidity. It is interesting to note that the incidence of laceration of the perineum was slightly less in those women whose delivery had been assisted by the forceps.

ITS ADVANTAGES

Anyone who has used the light instrument would expect this. The blades are so slight and apply themselves so accurately to the fœtal head that for practical purposes they do not prov[illegible] any added bulk to distend the vaginal outlet. [illegible] his respect Munro Kerr [7] writes: "as a matte[illegible] fact there is less bruising and injury with judici[illegible]mployment of forceps than if the head is permitted [illegible]ss unduly long upon the perineum." The accurate apposition of the instrument to the fœtal skull a[illegible]ows both forward and backward movement to be controlled by the handle. Thus one of the attendant's hands controls, and controls efficiently, the fœtal head and the other can be used to try to preserve the perineum. To control the spontaneous delivery of a fœtal head three hands really are required; one to prevent too rapid progress, one to prevent the head receding during the interval between contractions [illegible]nd a third to control the perineum. The light forc[illegible] combines the action of the hands which preve[illegible] too rapid progress and the receding of the head. [illegible]hat laceration of the perineum occurred less fre[illegible]ntly in the forceps cases in this series speaks for i[illegible] For in a certain number of these women the [illegible] delay was thought to be due, not to uterine in[illegible] but to the smallness of the vaginal outlet. [illegible]ould not apply to such an extent in women who were delivered spontaneously. The instrument has other added advantages. Its construction is such that it is impossible to exert a tremendous pull, and the risk to the child should in consequence be enormously decreased. The instrument cannot be applied to a fœtal head that is not well down in the pelvis and therefore only rarely before completion of the first stage of labour. It can be applied and has been applied without an anæsthetic when the woman required help in the last stages and the appreciation of the pains was sufficiently dulled by the previous administration of analgesic drugs. In any case, only the lightest anæsthetic is required for its application. The small size of the instrument moreover greatly facilitates the ease with which it is sterilised.

Conclusion

Taking into consideration the facts outlined above and with the firm belief that the really low forceps operation is virtually without risk to the mother or child, I hold that it would be better to advocate a more liberal use of the short light forceps at the end of labour than, turning a blind eye to what is obviously a universal practice, to teach the strictly limited use of another instrument which is far too clumsy and heavy for this purpose.

THE VALUE OF BREATHING EXERCISES IN ASTHMA

BY JAMES L. LIVINGSTONE, M.D., F.R.C.P. Lond.
PHYSICIAN, KING'S COLLEGE HOSPITAL; ASSISTANT PHYSICIAN, HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON; AND

MARJORIE GILLESPIE, M.D. Glasg.
HAGUE ASTHMA RESEARCH SCHOLAR

(From the Asthma Clinic, King's College Hospital)

THE remedial value of breathing exercises in asthma has been known for many years and has been practised by the medical profession in this country and abroad. On the continent Dr. L. Hofbauer, of Vienna, claims excellent results from humming exercises in his book on the treatment of asthma.[1] In this country breathing exercises have been used as an adjuvant to other forms of treatment in various physiotherapeutic departments, including those of Guy's,
the Hospital for Sick Children, Great r having so
and King's College Hospital. , No. 27, also,

College Hospital, and Miss Seyfang agreed to treat asthmatics in the clinic by this means. Her results suggested that research, in properly controlled cases, might show the type of patient likely to benefit from this form of therapy. After arrangements for carrying out this research had been made, Miss Seyfang unfortunately found herself unable to continue her work at King's College Hospital and resigned in December, 1932.

As the universally recognised aim of respiratory exercises in asthma is the education of the patient in the proper control of the diaphragm, together with mobilisation of the chest wall, a series of exercises was drawn up by Dr. E. B. Clayton and his assistants in the physiotherapeutic department with these objects in view. They are well-recognised, simple exercises and have been practised by the patients forming the subject of this investigation. Those used by Miss Seyfang differed only in detail.

The cases under consideration have been closely observed for a period of from one to two years and the clinical condition of each has been assessed twelve months after the beginning of treatment, thus allowing for seasonal variations in the severity and frequency of attacks. We are aware that one year is too short a time in which to judge the permanence of results, but we hope to follow up these and other cases and make a further report at a later date.

The aim of this investigation was to observe the results of treatment by breathing exercises alone. For proper scientific control frequent observation of the cases over a period of at least two years would have been necessary and every other form of treatment, including drugs, should have been prohibited; in the asthmatic even a placebo of brown sugar in water might have a psychological effect. In practice we found it impossible to enforce such rigid control, as the mentality of the hospital type of patient requires something concrete—the bottle of medicine or pill—as an incentive to regular attendance. Again all the patients without exception had been taking various remedies obtained from their family doctor or from the chemist, the type and dose of which we could not control. We decided that the only practical course was to prescribe certain simple drugs ourselves and to forbid all other treatment. The drugs were gradually withdrawn as the patients gained confidence in the exercises, commonly in 4–8 weeks.

THE AIMS OF BREATHING EXERCISES

During an attack, in which the bronchioles are narrowed by spasm and congestion, there is a valvular action whereby air drawn in by the strong inspiration can enter the alveoli but cannot escape. Accordingly the asthmatic has difficulty in expiration. The chest is over-distended, air is pent up in the lungs, and there is insufficient gaseous exchange, i.e., a condition of gross *functional* emphysema. When the attack passes off, conditions return to normal. During an attack the breathing is of the thoracic type and the accessory muscles are fully contracted. The diaphragm is depressed to its maximum extent and is seen to be making spasmodic contractions or none at all. The more dyspnœic the patient becomes the more he endeavours to *inspire* and so over-distends his already fully inflated lungs. In chronic cases the
ai typical permanent asthmatic def ci mity of the chest
bro sults—kyphosis, pigeon chest, en Harrison's sulcus.
1/1 is is due to actual shorten the fibres of the
T phragm, intercostal and d in thy muscles from
deper onged spasm. The ches ost of tion at the fourth
diaphi decreased to about 1 there wa e vital capacity

is grossly diminished. For these reasons the aims of breathing exercises should be :—

1. To empty the lungs by increasing the expiratory phase.
2. To re-educate the automatic diaphragmatic movements and to diminish the thoracic type of breathing.
3. To relax spasmodically contracted muscles.
4. To mobilise the ribs and chest wall and to correct kyphosis.

Various types of simple exercises can be devised to fulfil these requirements and examples of such exercises are given in a booklet recently published by the Asthma Research Council (1934).[5]

We find it best to teach patients to take a *short* inspiration through the nose and then to make a *long* expiration through the mouth, with a whistling or hissing noise; this concentrates the attention on the expiratory phase. During expiration the epigastrium must sink in, to ensure that the diaphragm rises in the chest. (Female patients are forbidden to wear tight corsets.)

A good deal depends on the personality of the teacher: she must gain the patient's coöperation in practising the exercises two or three times daily for at least ten minutes, over a prolonged period; she must also try to enthuse him with the benefit he is likely to obtain from the treatment. She must warn him that at first the exercises may make him worse by causing coughing and wheezing, which are produced in the majority of cases on full expiration. This loosens the mucus, which is presently coughed up, to the patient's relief. She must also persevere until the patient acquires habitual diaphragmatic breathing.

The patient is encouraged to practise the exercises, gently, when he feels an attack is imminent, in order to abort it.

ROUTINE OF INVESTIGATION AND TREATMENT

In each case a complete history was taken and a clinical examination made, including measurements of the chest expansion and screening of the diaphragmatic movements. In all cases suspected of nasal disease a laryngologist's report was obtained. The home conditions were investigated in considerable detail by the almoner's department; every patient kept a record of his attacks or wheezing in a notebook, which was inspected at each visit to the clinic.

Of the routine investigations, only those relevant to the subject will be discussed in this paper; the results of the remaining investigations will be dealt with in separate articles.

As far as possible all cases were treated in the same way. Attendance for instruction in breathing exercises was required twice weekly at first and at longer intervals as the patients progressed. During the first few weeks of treatment a mixture containing Potassium Iodide gr. v., Tinct. Camph. Co. ℳ xlv., and Tinct. Stramonium ℳ x., was given in some cases, and ephedrine or ephazone tablets for the attacks; these drugs were withdrawn as the cases improved. The patients were instructed not to take late meals. Other therapeutic measures, such as vaccines, nasal operations, and removal of sensitising proteins (feathers, dust, foods), were rigidly avoided, even though they were obvious causative factors, in order that the full value of breathing exercises might be gauged.

CLINICAL RESULTS

It is difficult in an alternating and paroxysma condition such ;orc·sthma to assess the results ,e treatment in a at an·ic manner; as has been sne before, we do n·robable·der that a year's observa·ere is sufficient to ·ise, and he use of the term "cur·y's in any case. A·pra-orbit., we have used the foll·elvic terms as conveying best, in our opinion, the varying gradations of the patient's condition :—

Excellent (E.).—Cases free from all wheezing or attacks of asthma but still doing breathing exercises.

Very good (V.G.).—Cases having an occasional wheeze but no real attacks; still doing breathing exercises.

Much improved (M.I.).—Cases which are very much better, although still having occasional attacks and wheezing.

Improved (Imp.).—Cases showing only slight improvement.

Failure (F.).—Cases showing no improvement, although the exercises have been conscientiously practised.

This report is based on the study of 75 cases, of which 38 were male and 37 female. The ages varied from 3 to 75 years, 21 cases being under 15 years of age. Other manifestations of allergy (hay-fever, eczema, and so forth) were found in 32 cases. A family history of allergy was found in 51 cases.

The cases were divided into two groups, "allergic" and "bronchitic."

By *allergic* is meant cases which are hypersensitive to certain substances, as judged from their history or response to skin tests. As a rule the onset of symptoms is in early life, and there is a positive family history of other allergic conditions—namely, hay-fever, eczema, migraine, and urticaria; 49 cases came into this group.

By *bronchitic* is meant cases in which the asthma seems to follow or be related to bacterial infection of the respiratory tract; 26 cases came into this group.

Table I. shows the clinical results, at the end of one year, of a group of 75 cases treated by breathing exercises alone and compared with a control group of 50 similar cases, in which the treatment has been specially selected, e.g., removal of various antigens (feathers, dust, foods, &c.) to which the patients were sensitive, vaccines for the bronchitic type, nasal operations, hydrochloric acid for the achlorhydric, and various specific and non-specific desensitisation for others.

unconscientious cases; this type of patient will probably prefer desensitisation treatment, which depends on the physician's efforts rather than on his own. We are trying to show that there is a simple form of therapy which gives good results in those patients who are anxious to help themselves.

The relation between the clinical results and the duration of the disease shows, as would be expected, that the longer the duration of the condition the greater the number of failures:—

,, 1 ,, 5	32	4
Under 1	7	0

In this series the females seemed to do better than the males, 27 out of 37 cases being very much improved as opposed to 25 out of 38 males. This holds true for all ages. The number of cases is of course too small for any generalisation.

The nomenclature used in Table I. does not quite show the difference between patients who before treatment had had daily attacks which were reduced later to one or two per week, and patients who before treatment had only a few attacks per annum which were reduced later to about half the number. Both are classed as "improved." In order to bring out this difference we have prepared a table based on the number of attacks before and after treatment, as defined by each patient in their asthma record books. This method of assessment corresponded very closely with the nomenclature used in Table I. A few examples are given in Table II. to show the details recorded. The table shows the basis of our clinical classification, and gives a good idea of the progress of the case. For example, Case No. 94, a housemaid, although still having slight daily wheezes, is no longer having so many or such severe attacks. Case No. 27, also, although having more wheezing than before, is getting fewer and far less severe paroxysms; he expresses himself as being "very much better." We have grouped him under the heading "improved" rather than "much improved" because he is ha[illegible] more frequent wheezes than before.

DIAPHRAGMATIC MOVEMENTS

Observation of the diaphragmatic [illegible]ments by screening before treatment sho[illegible]d excursion in 38 of the 75 cases. Sixt[illegible] the cases were re-screened after treatment. In many of these we observed a very big excursion of the diaphragm. As would be expected, before treatment was begun good diaphragmatic movements were found in a larger proportion of the males than of the females. However, after treatment, when the females had learned to use the diaphragm, this difference was no longer apparent.

CHEST MEASUREMENTS

The chest expansion at the level of the fourth rib and of the epigastrium was measured before treatment and afterwards at three-monthly intervals. Before treatment, in most cases, the chest expansion was poor, especially at the epigastrium, whereas afterwards it improved. Those patients who had naturally a good epigastric expansion, or acquired this with treatment, improved clinically and vice versa. The actual measurements varied with the type, age, and sex of the individual, but on the whole an expansion of at least 2½ in. at the fourth rib and 2 in. at the epigastrium was obtained by those who improved markedly as regards their asthmatic condition. Details of these observations will be given in a subsequent paper on respiratory efficiency in asthma.

OBSERVATIONS BY THE PATIENTS

About half of the patients who have done well clinically state that they can abort all but very severe attacks by doing breathing exercises. Many of the bronchitic cases also find that, although they still have attacks of bronchitis, these are no longer accompanied by attacks of asthma. A few patients say that they have far less bronchitis than formerly.

DISCUSSION

The results show that half of the cases, 38 out of 75, are, for all practical purposes, symptom-free. In a further 14 the clinical condition is markedly improved. Considerably better results have been obtained in the allergic than in the bronchitic group. This difference is mainly accounted for by repeated attacks of bronchitis in the winter months; better results in the bronchitic group are, in our view, likely to be obtained by combining vaccine therapy with breathing exercises. (Incidentally asthmatic patients are very much more sensitive to vaccines than ordinary bronchitics, and should be given not more than 1/100 of the average dose.)

The better results obtained in the female cases depend on the fact that most of these were poor diaphragmatic breathers; there was consequently more scope for improvement among them and a larger proportion acquired control of the diaphragm after breathing exercises. An important factor in this connexion is that the females had discarded tight corsets, which entirely prevent natural abdominal breathing. The age of the patient did not appear to influence the clinical improvement as much as did the duration of the disease. Indeed, it is surprising to observe the degree of chest mobility and diaphragmatic movement obtained in some of the elderly patients.

In comparing the control group, in which treatment was specially selected, with the group treated by breathing exercises alone, the proportion of good results is seen to be practically the same. This, in our opinion, points to the value of breathing exercises as a practical form of therapy, since equally good results were obtained with this simple treatment as with the more complicated and specific measures practised in the control group.

When the movements of the diaphragm and epigastrium are considered in relation to the clinical results, it appears that patients with good movements originally did better than those with poor movements; if, however, the latter acquired good movements the clinical condition was also for the most part improved. For success it is necessary to obtain: (*a*) A chest expansion at the fourth rib of at least 2½ in. (*b*) An epigastric expansion of at least 2 in. (*c*) A good diaphragmatic excursion during normal breathing. (*d*) Complete control over the full range of diaphragmatic movement. (*e*) The ability to dissociate thoracic from abdominal breathing at will. In addition to these purely physical aspects, there is also a psychological aspect of this treatment: (*a*) The patient is encouraged to aim at aborting the attacks by the exercises. (*b*) It is thereby suggested that the treatment lies in his own hands. (*c*) This régime entails a certain amount of perseverance and effort on the part of the patient and is therefore excellent discipline.

SUMMARY

(1) In 75 cases of asthma treated for one year with expiratory breathing exercises, good clinical results were obtained in 52, improvement in 12, and no improvement in 11 cases.

(2) The improvement seemed to depend upon the patient acquiring mobility of the chest, natural diaphragmatic breathing, and control of the diaphragm. There is also a considerable psychological factor.

(3) The treatment requires perseverance and effort on the part of both patient and teacher over a considerable time.

(4) A number of patients were able to abort impending attacks by these exercises; this appeared to be due to loosening and expulsion of mucus, rather than to any other factor.

(5) This method of treatment is simple and applicable in all cases; it is sound treatment from the physiological point of view. In this series 11 out of 75 cases were unable to learn diaphragmatic control.

(6) In spite of the fact that good results are claimed from breathing exercises alone, it is held that specific treatment should not be neglected—e.g., removal of feathers, foods, and so forth—or operation in gross nasal disease.

Our thanks are due to Miss Dorothy Hague who founded the Hague Asthma Research Scholarship, which one of us (M. G.) has held, and to the anonymous donors who provided funds for the apparatus and general expenses. We are especially grateful to Miss C. I. Mackness of the almoner's department and to Mrs. M. K. Stratford and Miss J. M. Reed of the physiotherapeutic department, whose perseverance and hard work have been invaluable.

Lastly we thank the patients forming the subject of this reasearch, who have undergone, without complaint, the discomfort associated with the repetition of the various investigations.

STABILISATION OF THE ACROMIOCLAVICULAR JOINT

BY CECIL P. G. WAKELEY, D.Sc. Lond., F.R.C.S. Eng., F.R.S.E.

SENIOR SURGEON, KING'S COLLEGE HOSPITAL AND WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM; CONSULTING SURGEON TO THE MAUDSLEY HOSPITAL AND TO THE ROYAL NAVY

THE acromioclavicular joint is essentially stable and secure, owing these qualities not so much to the capsular ligament investing the joint as to the coracoclavicular ligament, an extracapsular ligament which has no direct connexion with the joint itself. Were it not for the conoid and trapezoid ligaments, the component parts of the costoclavicular ligament, this joint would be relatively weak and dislocation would of necessity occur frequently. The anterior components of the trapezius and deltoid muscles attached above and below the outer end of the clavicle respectively, help to stabilise the joint further.

ANATOMY

The articular surfaces of the clavicle and acromion respectively are cartilage-clad, ovoid areas, the long axis of which is from before backwards. Further, the articular surfaces are so inclined that the clavicular surface looks downwards and outwards, while that of the acromion faces upwards and inwards. The ligamentous capsule investing the joint is complete, but is somewhat thicker above and below than it is in front and behind. Between the two articular surfaces is a very variable interarticular disc which is usually incomplete, but in rare cases may be complete and then subdivides the joint into two independent synovial cavities. Owing to the configuration of the two articular surfaces, in the form of two inclined planes opposed one to the other, the outer end of the clavicle is liable to be so relatively displaced as to ride upwards and outwards upon the acromion. This may occur without any disturbance of the coracoclavicular ligament, and results in a partial dislocation or subluxation of the joint.

Should the region of the point of the shoulder be the seat of very severe trauma, the outer end of the clavicle is usually fractured. Occasionally, however, complete dislocation of the joint, which can only occur when the coracoclavicular ligament is ruptured and the neighbouring muscle damaged, results (Fig. 1). In such cases the outer end of the clavicle may be displaced: (1) upwards; (2) backwards and downwards; (3) forwards and downwards;

(4) backwards, depending upon the direction in which the dislocating force is applied. In complete dislocation the outer end of the clavicle is most commonly displaced upwards, an accident which may result from a sudden violent thrust impinging downwards upon the acromion, and often accentuated by contraction of the trapezius muscle. If the severity of the dislocation is uncertain, the injury should be examined radiographically in order to determine whether the coracoclavicular ligament is ruptured or not. When this ligament is ruptured, a small flake of bone torn from the under side of the clavicle is often visible in the radiogram.

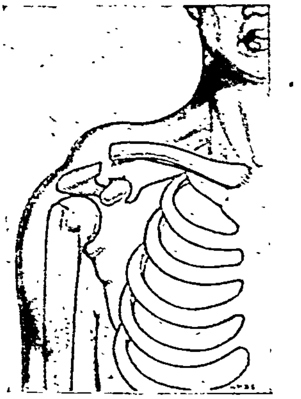

FIG. 1.—Drawing from a skiagram showing a complete dislocation of the acromioclavicular joint.

TREATMENT

Subluxation of the coracoclavicular joint, when the outer end of the clavicle is displaced upwards and outwards upon the acromion, is easily reduced. The shoulder should be raised and carried backwards while the outer end of the clavicle is subjected pressure downwards. The arm is placed at the s

Although I have
times since 1915, an
before I had the op
sis five years later. on whom I first operated. This prompted me to investigate the results of the other four cases.

Case 1.—A. B., aged 25, a baker, was thrown from his cart in October, 1914, when his horse bolted. He fell on to the point of his shoulder and on admission to hospital was found to have a dislocation of the outer end of his clavicle. This was confirmed by radiography, and the joint was immobilised with strapping. After three weeks the strapping was removed and the patient wore a sling for two weeks while he attended for massage and electrical treatment. He returned to work in December, some seven weeks after his accident, but soon found that he could not do any work in the bakery which necessitated using his shoulder muscles, as the bone became displaced and hurt him. H was examined again in January, 1915, and found to ha complete dislocation of the acromioclavicular joint wing to the free mobility of the outer end of t it was decided to stabilise the joint by a wi unding the joint. This was performed ac ethod described above, and the patient hospital on the fifteenth day and w ks after his operation. In Januar rated upon for acute appendic y. His acromioclavicul o be absolutely stable ver had any troub years previou ult was could

198	M.	44	6	1	Nil.	1·3	1929.	G.-ent.
199	M.	38	8	22	28·7	35·7	1926.	
200	M.	42	8	19	19·6	21·7	1926.	

From Table I. it will be seen that the average subsequent yearly sick absence of the manual group was 15·6 days for digestive disorders and 28·7 days for illness of all sorts. For the non-manual group the average was 9·4 days for digestive disorders and 21·1 days for illness of all sorts. Of the whole group of 200 cases 24 per cent. incurred an average subsequent yearly incapacity for work of less than a week; 16 per cent. of from 7 to 14 days; 26·5 per cent. of from 14 to 28 days; and 33·5 per cent. of more than a month.

From Table II. it will be seen that the average subsequent yearly sick absence of the manual group was 12·5 days for digestive disorders and 26·1 days for illness of all sorts. For the non-manual group the average was 10·5 days for digestive disorders and 16·2 days for illness of all sorts. Of the whole group of 40 cases, 11 incurred an average subsequent yearly incapacity for work of less than a week; 8 of from 7 to 14 days; 12 of from 14 to 28 days; and 9 of more than a month.

From Table III. it will be seen that the average subsequent yearly sick absence of the manual group was 15·5 days for digestive disorders and 26·9 days for illness of all sorts. For the non-manual group the average was 10·7 days for digestive disorders and 19·7 days for illness of all sorts. Of the whole group of 150 cases 24 per cent. incurred an average subsequent yearly incapacity for work of less than one week; 16·7 per cent. of from 7 to 14 days; 29·3 per ce of from 14 to 28 days; and 30 per cent. of more tl a month.

37	M.	50	9	9	0·3	5·1	1923.
38	M.	49	10	26	16·7	40·6	1921.
39	F.	30	15	57	18·3	29·3	1920.
40	M.	37	13	9	2·0	4·5	1922.

(*ll*) Gastro-enterostomy for pyloric stenosis 7½ years late

From Table IV. it will be seen that the aver subsequent yearly sick absence of the manual gr was 16·4 days for digestive disorders and 30 d for illness of all sorts. For the non-manual gr the average was 12·1 days for digestive disorders 21·4 days for illness of all sorts. Of the whole gr of 40 cases, 4 incurred an average subsequent ye incapacity for work of less than a week; 11 of fr 7 to 14 days; 10 of from 14 to 28 days; and 1 more than a month.

It has been impossible, owing to exigencies of spac print in detail in the tables each individual sick rec but the number of separate occasions, during the y of observation, given in the fifth column, will help to su some idea of the distribution of the sick absence. very large proportion of the cases observed it was more or less uniform character throughout the obse years.

GENERAL CONCLUSIONS

In so far as the above groups can be consid representative, it would appear that, while there many individual instances of subsequent good he the general expectation of working incapacity in c of proved duodenal and gastric ulceration—how of proved duodenal and gastric ulceration—how treated, and under ordinary industrial conditio is definitely high.

Thus of the 430 cas[illegible] under observation 31·6 cent. incurred an av[illegible] sequent yearly incapa for work of [illegible] onth; 27·7 per cen

Part. gast. = partial gastrectomy. C.V. = carcinoma ventriculi.

(t) Second operation 12 months later. Gastro-enterostomy.

(u) Gastro-enterostomy. Second operation six years later. Partial gastrectomy.

(v) Duodenal ulcer three years later. Gastro-enterostomy.

(w) Contracted abdominal tuberculosis eight years later.

(x) Perforation (subacute).

(y) Sixteen months later, gastro-enterostomy.

(z) Second operation for adhesions eight years later.

(aa) Twelve months later gastro-jejunostomy for duodenal ulcer.

(bb) Pulmonary tuberculosis five years later.

(cc) Second operation for duodenal ulcer six years later.

(dd) Perforation five years later. Duodenal ulcer seven years after original operation.

(ee) Died after second operation six years later.

(ff) Operation for duodenal ulcer four years later.

(gg) Second operation 18 months later.

(hh) Second operation two years later.

(ii) Second operation one year later for perforation.

(jj) Second operation one year later.

(kk) Second operation 18 months later for duodenal ulcer.

from 14 to 28 days; 17·7 per cent. of from 7 to 14 days; and 23 per cent. of less than a week—the last-named, from the standpoint of regular working capacity, representing the undoubtedly good results.

Of the 200 cases in the duodenal operation series, 4 afterwards developed gastric ulcers, and 6 required a second operation for the original condition. Of the 40 duodenal cases medically treated, 5 required operative treatment later. Out of the whole group of 240 cases of duodenal ulcer, 4 afterwards developed pulmonary tuberculosis, a proportion large enough to suggest a generally lowered resistance.

Of the 150 cases in the gastric operation series, 6 afterwards developed duodenal ulcers and 9 required a second operation for the original condition; 1 developed pulmonary and 1 abdominal tuberculosis, and 1 carcinoma of the stomach.

It has sometimes been held, from a surgical point of view, that perforated cases, for some obscure reason, have a better subsequent record than others. But in the above groups this has not proved to be the case. In the duodenal operation series, the subsequent average annual sickness incurred in the perforated cases (24) was 16·1 days for digestive disorders and 29·3 days for illness of all sorts, as compared with 12·6 days for digestive disorders and 25 days for illness of all sorts in those where perforation had not taken place. In the gastric operation series the average annual sickness in the perforated cases (41) was 14·8 days for digestive disorders and 23·8 days for illness of all sorts, as compared with 13·9 days for digestive disorders and 25·2 days for illness of all sorts in those where perforation had not taken place.

Turning to the age-distribution, it will be seen that, of the 240 cases of duodenal ulcer, 48 were under thirty-five years of age when the condition was operated upon or otherwise confirmed, 137 between the ages of thirty-five and forty-five, and 55 were forty-six or over. Of the 190 cases of gastric ulcer, 51 were under thirty-five years of age when the condition was operated upon or otherwise confirmed, 85 were between the ages of thirty-five and forty-five, and 54 were forty-six or over. The condition in both series was therefore predominantly one of middle and later life. Although the average yearly sick absence incurred is very considerable in all groups, the type of work performed—manual or non-manual—appears to have a not unimportant bearing on the amount of such sick absence. It will be noted, in the whole series of cases, that manual workers had an average sick absence for all causes of approximately 8 days per year more than the non-manual employees.

Finally there is a general impression that irregularity in the hours of employment and consequently, to some extent, of meal-times may be a predisposing factor in the development of gastric and duodenal ulceration. It has not been possible in the above series to obtain exact data either in support or denial of this. But in this connexion an analysis of a year's sick absence in large groups of employees, made some years ago, may be of interest. In the year in question, 1926, the sick absence incurred from duodenal and gastric ulceration in a group of 70,000 men, mainly engaged upon irregular duties, as compared with such sick absence in a group of 12,000 men of approximately the same status, mainly engaged upon regular duties, was in the proportion of 7 to 6, thus indicating that this factor was probably considerably less important than is usually supposed.

We should like to record our thanks to all those who have assisted in the collection and preparation of the above figures, and particularly to Mr. A. W. Scott, of the Medical Branch of the Post Office.

PUNCTATE BASOPHILIA IN RHEUMATIC CASES AFTER CHRYSOTHERAPY

By G. J. Griffiths, B.Sc., M.B. Lond.
PATHOLOGIST TO THE DEVONSHIRE ROYAL HOSPITAL, BUXTON; AND
Joseph Race, F.I.C.
BIOCHEMIST TO THE HOSPITAL

Examination of a Leishman-stained blood film from a case of myelogenous leukæmia showed definite punctate basophilic and polychromatic cells. On reference to the case-sheet it was found that the patient had received numerous injections, and as she had been sent into this hospital as a rheumatic condition it seemed possible that gold preparations had been used, and that some of the abnormal red cells might be due to this cause. Her private doctor was consulted on this point, and at the same time other patients receiving or known to have received gold injections were examined. In each case punctate basophils and polychromatic cells were found in the blood.

THE BLOOD PICTURE

So far, 21 cases treated with gold preparations have been investigated and out of these 16 contained both punctate basophils and polychromatic cells; no abnormal erythrocytes have been observed in untreated cases. Toxic symptoms developed in 5 cases; gastro-intestinal disturbances in 4 cases; and albuminuria in 1 case.

As the possibility that these abnormal cells might be present was not appreciated until this accidental finding, the exact time of their first appearance in the blood could not be ascertained; but the more recent cases have been carefully investigated so as to determine the earliest possible moment at which these cells can occur in the course of treatment. Out of 5 patients receiving two injections each, with an interval of 1 week between each injection, polychromasia and punctate basophilia appeared in 4, the patient with no abnormal blood picture having albuminuria. Out of 5 patients receiving three injections each, with an interval of 1 week between each injection, polychromasia and punctate basophilia appeared in 4, the fifth being free from toxic symptoms. Thus it can be stated that these primitive cells can appear after a second, if not a first, injection of gold.

The length of time during which these cells persist in the blood following the last injection of gold has been more readily ascertained. In one case, two courses of gold were given and punctate basophils and polychromatic cells were found 5 months later; in another, after eight injections, the last being 3 months ago, the blood showed the same condition. Another patient to whom gold injections were given 10 months ago revealed abnormal cells, whilst a patient receiving gold 12 months ago showed no abnormality of the red cells. The evidence obtained up to the present thus indicates that these abnormal cells may persist for at least 10 months.

The gold preparations used in the cases examined were sanocrysin and myocrysin. Of 9 cases treated by myocrysin all showed polychromasia and punctate basophilia, whereas, of those treated by sanocrysin, only 1 showed abnormal cells and 1 albuminuria. The dosage given does not seem to influence the appearance of primitive cells; they were observed in 1 case after two injections, equivalent to 0·15 gramme of myocrysin. It is perhaps of interest to note that Gaul and Staud[1] were able to detect gold spectroscopically in the cutis after a dosage of 0·1 g. of gold.

Little deviation from the normal was found in the total red count and in the percentage of hæmoglobin following one or two injections of gold, except possibly for a slight reduction in the total red count which soon adjusted itself to its normal figure. In all the cases examined there was a reduction in the total white count, the average being 4000 to 5000 per 1 c.cm. with a decrease in the percentage of polymorphonuclear cells and a corresponding relative increase in the lymphocytes. The average number of punctate basophils per 100 white cells counted was 3 to 4 cells, but in one case the number in two consecutive counts with an interval of 4 days showed 31 punctate basophils per 100 white cells counted. This patient had received three injections of myocrysin, the total amount being 0·11 g. Polychromasia and punctate basophilia were observed in all the counts made. There were no primitive red cells other than those mentioned.

Attention has previously been drawn to the toxic effect of gold injections and to certain changes in the blood of patients undergoing gold treatment.[2]

The more important changes in the blood were: an increase in the coagulation and bleeding time as observed by Jacquelin and Allanic[3]; leucopenia, with a relative lymphocytosis and an increase in the percentage of eosinophils as observed by Archard and others[4]; and thrombopenia by Secher,[5] in one of whose cases the platelets were reduced to 22,000 per c.mm. following injections which totalled to 1·5 g. of sanocrysin. In his observations on the presence of punctate basophilia as a result of lead therapy for the treatment of malignant disease, Brookfield[6] found, in the early stages, a temporary anæmia due to the destruction of the red cells, this being most conspicuous immediately after the injection of lead and while it was circulating in the blood stream. He observed no change in the white cells and little effect, if any, on the platelet count.

Following the observation of Secher[5] that the effect of gold on the blood platelets is to produce thrombopenia, we have made platelet counts before and during gold treatment of rheumatic patients. In 36 counts no obvious change was observed although the total amount of sanocrysin used in some cases exceeded the figure of 1·5 g. quoted by Secher. Little importance can be attached to the leucopenia with a relative lymphocytosis already mentioned, since this is frequently found in chronic rheumatoid arthritis even before treatment with gold preparations. The highest percentage of eosinophils found in a gold-treated patient was 8, a value which we and others have found equalled in untreated cases.

EFFECTS OF GOLD AND LEAD COMPARED

There is a close relationship between lead and gold injections in that both produce a temporary anæmia; moreover, punctate basophils and polychromatic cells appear in the blood following minute doses, and even after the first or second injections, of heavy metals. Following the use of both gold and lead there is a tendency to return to normal after the injections have been stopped, although with gold preparations it may take nearly 12 months from the date of the last injection.

Various hypotheses have been suggested as to the effect of gold on the circulating blood. Bousser and Weil[1] state that it produces an intoxication of a specific nature in the blood itself or on the bacteria circulating in the blood which, so altered, produces a change in the elements composing the blood. Jacquelin and Allanic[3] suggest that some patients have an idiosyncrasy to gold. Our results have no bearing on the former hypothesis, and the fact that we have found abnormal red cells in a great majority of gold-treated cases lends no support to the suggestion of Jacquelin and Allanic.

In view of the similarity in the blood picture following lead gold therapy it is probable that gold, like lead, causes a local concentration of the basophilic substance which is normally evenly distributed, and so produces the punctate basophilia and polychromasia also found in immature cells. The changes produced by lead and gold are, however, probably reversionary and due to toxic degeneration. Secher[5] emphasises the advantage of using small doses of gold with long intervals between the injections, and we consider this to be a sound policy.

We express our indebtedness to Dr. C. W. Buckley, senior physician to the hospital, for access to many of his cases, to Dr. G. C. Pether for his help with the references, and to our technical assistant, Miss M. Harrison, for the examination of many of the blood films.

LIPIODOL AS A THERAPEUTIC AGENT

By Gordon Harrower, M.B., Ch.M. Glasg.,
D.Sc., F.R.C.S. Edin., F.R.S.E.

CONSULTING SURGEON TO THE GENERAL HOSPITAL, SINGAPORE;
PROFESSOR OF ANATOMY AT THE KING EDWARD VII.
MEDICAL COLLEGE, SINGAPORE

THE value of lipiodol in diagnosis is now well recognised, but its beneficial effect on certain inflammatory conditions may not be generally appreciated. The following cases may encourage others besides myself to use it as a means of treatment.

THE FIRST CASE

A Hokien Chinese woman, aged 26, was admitted to hospital on Feb. 6th under Prof. J. S. English, complaining of severe pain in the joints of the arms and legs, starting about three months previously. Though present in all her joints, it was worst in the small joints of the hands and in both knees, constant, being without intermission. In the other joints there was a vague aching sensation. The knee-joints were maintained in extreme flexion and attempts at extension produced severe pain. There was no thickening of peri-articular structures. Movements at the right elbow-joint were restricted and the interphalangeal joints were in flexion with extension of the metacarpo-phalangeal joints. The thenar and hypothenar eminences of both hands were wasted, more on the right side. No thickening of the ulnar nerves was elicited and the tests for leprosy were negative.

The lower abdomen was found to be tender and she had amenorrhœa and foul-smelling vaginal discharge which dated back to an abortion three months before. The cervix was found to be eroded, the uterus retroverted and retroflexed but not enlarged. The appendages were prolapsed without thickening or tenderness. Vaginal smears showed Gram-negative and Gram-positive cocci in profusion. Nothing of note was discovered elsewhere in the body. There was no fever and the pulse-rate was normal.

prejudicing the life or well-being of mother or child. In this short series all the infants were delivered alive and well, with the exception of one fœtus which had no bone formation in the vault of the skull. There was no maternal morbidity and the incidence of laceration of the perineum was slightly less in those women whose delivery had been assisted by forceps. It has of course yet to be proved that these forceps are as harmless in the hands of the general practitioner as in those of an expert. The tendency of modern operative technique is to use mechanically efficient instruments, which the operator can control with little muscular exertion of his own. It might be argued also that a short light forceps would be of little use in expediting a case of tedious labour with early rupture of the membranes, slow dilatation, a large caput, and marked moulding. The caput may show but the skull may be still far from the perineum, held up perhaps by the ischial spines. These are the cases where forceps are really required, and where longer ones are, if not essential, certainly more conveniently applied.

The orthodox obstetrician will doubtless find much to say in his own defence. He may suggest that the practice in the particular home selected represents that not of the best but of the most fashionable obstetricians, and that these achieve and maintain their popularity by pandering to their clients' desire for a speedy and relatively painless delivery rather than one which offers the utmost degree of safety to mother and child. It may be said, too, that if London practice is mirrored by that in this particular home it falls short in excellence of that at other centres. But when all has been said in defence there will remain an uneasy feeling that there is a good deal of truth in the suggestion that forceps are used and probably will always continue to be used in order to expedite the final stages of a normal delivery. The expert obstetrician is not likely to be tempted to use a more powerful instrument at an earlier stage just because he has it in his bag. But the practitioner may well learn to have a far greater respect for the axis-traction forceps if the veto which forbids him to use it except in grave emergency is accompanied by permission to help the weary patient to complete her labour with an instrument which is adapted for that purpose only.

ANNOTATIONS

INFANT MORTALITY ONE HUNDRED YEARS AGO

THE absence of the systematic registration of births and deaths makes it difficult in this country to trace at all accurately the course of mortality before the founding of the General Register Office in 1837. The figures upon which most workers have relied have been those contained in the London Bills of Mortality. In New York the difficulties appear, according to a recent paper by Charles Bolduan and Louis Weiner,[1] to be equally acute and to have lasted to a much later date; the registration of births was not established there until 1853, and even then for many decades was notoriously incomplete. In computing the infant mortality-rates of the nineteenth century these authors have therefore had to make an estimate of the births at each point of time from the populations recorded at ages under five at the census enumerations, or to work from conjectured birth-rates in each decade.

The result of their calculations is somewhat surprising. During the early part of the nineteenth century they find that the infant mortality-rate was relatively low—about 120 to 140 per 1000. It then rose steadily to a maximum of about 230 during the 'sixties, since when there has been a continuous and steep decline to a rate of about 60 in recent years. The unexpectedly favourable rates of the beginning of the century might be due to incompleteness in the reported deaths, and the subsequent rise to an improvement in their registration. But satisfaction on that point needs local knowledge, and Bolduan and Weiner from their inquiries are satisfied that the prevalence of low rates during the earlier years must be accepted as a fact, although the actual figures can, of course, be regarded as only approximately correct. The local situation also supports, they suggest, the validity of the picture. In the first quarter of the nineteenth century manufacturing was relatively unimportant in New York, whose inhabitants were mainly devoted to trade and shipping, housing conditions were generally favourable, and immigration from overseas was not yet well under way. The second quarter brought profound changes. The growth of population accelerated, factories increased, the standard of living fell through the competition of the increasing immigrants, and overcrowding and insanitary housing became prevalent. These conditions lasted through the 'fifties and 'sixties and led to the foundation of the present Department of Health with its subsequent improvement in the environmental conditions of the city and in its mortality experience. Such changes in conditions make it reasonable, the authors suggest, to accept their conclusion from the statistics that the infant mortality-rate was no higher at the beginning of the nineteenth century than at its end. That conclusion would in all probability be true of London, but the changes in level throughout the hundred years shown by Bolduan and Weiner in New York were certainly not present in London. Apart from spasmodic fluctuations from year to year the rate showed very little movement. From 1841 to 1901 it lay fairly steadily between 150 and 170 per 1000, and Brownlee's study[2] of the Bills of Mortality suggests that it was very little higher (about 180 per 1000) at the end of the eighteenth century. During that century there seems little doubt that child mortality, and probably infant mortality, fell heavily. Brownlee's figures for the death-rate under two show a rate in 1791–1800 only, roughly, half that calculated for in 1731–40, while J. R. Edmonds, an early contributor to our columns,[3] reached the conclusion that the death-rate under five was in 1810–30 less than half its level in 1730–50.

The London and New York figures, therefore, show very little likeness to one another. The London infant mortality-rate was probably improving in the eighteenth century, showed very little change throughout the nineteenth, and began its precipitate decline, in common with the rest of the country, at the turn of the twentieth. The New York experience, on the other hand, shows in Bolduan and Weiner's figures a material worsening throughout the first half of the nineteenth century, followed by an unbroken improvement from 1870 onwards—a generation before the corresponding movement in London.

TONSILLECTOMY

TONSILLECTOMY should now have been fashionable long enough for some agreement on its value to be reached. Dr. A. D. Kaiser, chief pediatrician to the Rochester General Hospital, New York, who has estimated that half the older children in the large American cities have had their tonsils out, found[1] that in a well-controlled group of over 2000 children whose tonsils had been removed, there did appear to be a slightly diminished incidence of scarlet fever and diphtheria, although there was an increased susceptibility to sinusitis, bronchitis, and pneumonia. Ulf Nordwall,[2] working at the Stockholm Hospital for Infectious Diseases, investigated the severity and complications of scarlet fever and diphtheria in groups of tonsillectomised and non-tonsillectomised children. For this purpose he classified his cases of scarlet fever into groups according to the extent and severity of the rash and the angina, and also according to the occurrence, number, and type of complications. He also made the wise provision of separating those cases in which extirpation of the tonsils was complete from those in which tonsillar remnants remained. From a total number of 104 tonsillectomised cases and 312 non-tonsillectomised controls, he concluded that not only had tonsillectomy failed to influence the severity of the onset as judged by the angina and the eruption, but also that there was no demonstrable influence on the complications with the possible exception of sinusitis, which appeared to be somewhat more frequent in the tonsillectomised patients. The figures relating to diphtheria had to be drawn from a smaller number of tonsillectomised patients, since most of the cases admitted to hospital suffering from diphtheria had intact tonsils. Over a six-year period, it was only possible to be certain of 71 tonsillectomised patients in a total of 1781 diphtheria admissions; these were compared with three times as many controls. The cases were divided into four groups, consisting of those with (1) mild reddening with or without small membranes on the tonsils; (2) more extensive membranes localised exclusively to the tonsils; (3) membranes extending beyond the tonsils but not covering extensive areas of the pharynx, and with some sign of virulence; and (4) signs of virulence and membranes covering large parts of the mouth and throat. Groups (1) and (2) were regarded as benign, (3) and (4) as malignant. The results showed that diphtheria of the pharynx was considerably more frequent amongst patients with tonsils than amongst those without, whereas nasal diphtheria was commoner amongst the latter; and that both malignant diphtheria and complications occurred much more often in the non-tonsillectomised cases. It would be curious if tonsillectomy proved to be more useful in the prevention and attenuation of diphtheria than in the prevention of the onset of complications of scarlet fever or rheumatism. With regard to the latter, Kaiser, in a recent summary[3] of the important points in the control of rheumatic disease in childhood, recording conclusions reached from a detailed study of 1200 rheumatic children, does not get us much further. All he can say from his material is that removal of the tonsils in children subject to attacks of tonsillitis or muscular pains will protect some children against the severe types of arthritis which have the highest mortality-rate in this disease. The figures available in this country[4] appear to support the American statistics. Although tonsillectomy is not as widely practised amongst the poorer classes, over 50 per cent. of public school boys have had their tonsils removed. The incidence of respiratory infections, sinusitis, and even catarrhal conditions appears to be, if anything, slightly higher amongst those who have been tonsillectomised than those who have not. In face of such evidence, there does appear to be a real need to temper the general optimism with which the operation is apt to be recommended.

BALANITIS

INFLAMMATORY conditions of the glans penis are often met with in practice, but medical text-books give little space to their description and not much help in distinguishing one form from another. In a recent review[5] Dr. John F. Madden enumerates various direct causes—namely, phimosis, congenital and acquired, trauma, chemicals, and non-specific bacteria. Erosive balanitis, which may lead on to gangrene and phagedena, has been shown to be caused by Vincent's spirochætes in symbiotic relationship with fusiform bacilli under anaerobic conditions. Favourable conditions for its production are the combination of a long tight prepuce with faulty hygiene. The disease is known to be inoculable from patient to patient, and for this reason it has been termed by Corbus and others "the fourth venereal disease." Dr. Madden takes the view that under suitable local conditions with lowered general resistance the disease may be produced by organisms normally present as saprophytes; it is therefore not necessarily venereal in origin. Balanitis due to the gonococcus without concomitant urethritis has been described, but must be very rare. Of the forms of balanitis occurring in the course of exanthematic diseases that associated with the early stages of syphilis is the most important. It is always imperative to exclude primary syphilis when balanitis is associated with phimosis. Cases have been recorded in which the primary stage has taken the form of a specific balanitis without demonstrable localised primary lesion, the so-called syphilis d'emblée. Balanitis associated with multiple pin-head erosions throughout the preputial sac may form the primary manifestation. Balanitis may also occur as part of the secondary stage of syphilis, especially as the result of extension to the glans penis and prepuce of a macular roseolar rash. The diagnosis of these conditions can usually be confirmed by microscopic demonstration of the *Spirochæta pallida* with darkground illumination, and this examination should never be omitted. Scabies, erythema multiforme, and various generalised eruptions due to internal medication are occasional causes of balanitis which fall into this group. Balanitis sometimes results from metabolic disorders, particularly diabetes mellitus; Dr. Madden states that some degree of balanitis is present in about 7 per cent. of all male diabetics. Retention of the sugar-laden urine in the preputia' sac gives rise to a secondary mycotic inflammator eruption. From the fact that this may be the first external indication of glycosuria, the importance of testing the urine for sugar in all cases of doubtful origin will be obvious. Other causes included in this group are the excretion of large amounts of phosphates, creatinine or urates in the urine, and ammoniacal fermentation due to incontinence or other cause. Certain local tissue changes may also give rise to balanitis. These conditions, which include kraurosis penis and leucoplakia penis, are relatively uncommon, but are important from the fact that they are known to be precancerous lesions. They are usually found in older men as the result of some chronic irritation. Dr. Madden describes a rare condition, balanitis xerotica obliterans, found in younger men, sometimes following circumcision for phimosis. Meatal narrowing may occur and complete occlusion of the urethra has been reported.

PLACENTAL EXTRACT IN MEASLES PROPHYLAXIS

THERE is, unfortunately, no reason to suppose that London will fail to experience within the next few months its biennial epidemic of measles, and although the value of convalescent or adult-immune serum in prophylaxis is fully accepted, it is unlikely that during the expected visitation the supply will prove anything like adequate to the demand. The difficulties which beset the collection of convalescent serum in sufficient quantities are obvious and perhaps insurmountable, but it should surely be possible by propaganda and organisation to secure in large numbers suitable donors of adult-immune serum. If, however, a reliable prophylactic were available which could be obtained more easily, the problems of public health departments during a measles epidemic would be greatly simplified. So far, measles-immune sera from other than human sources have not been proved to convey any appreciable protection, and the human donor has been the sole source of supply. Recently, however, the human placenta in its extra-corporeal phase has provided a promising alternative. On the ground of the known immunity of the new-born to the disease, C. H. McKhann and T. F. Chu [1] were the first to use placental extract in measles prophylaxis and, although its merits are not as yet fully attested, placental extract is issued commercially in the United States. The extract is prepared from the placentas of healthy white women with negative Wassermann and Kahn tests; the cord-blood must also show a negative W.R. The placentas are ground up and extracted with saline. The extract, freed from tissue and blood-cells, is precipitated with ammonium sulphate. The precipitate is dissolved in water, dialysed to remove salts, adjusted for protein-nitrogen content, and preserved with phenol. I. M. Levitas [2] has employed this preparation not only for prophylaxis but also for treatment in doses of from 1 to 2 c.cm. injected intramuscularly into the buttock. He records his opinion that the results in 25 out of 28 patients treated were excellent; but the 5 cases of which details are given provide no convincing evidence that placental extract is of any greater value in the *treatment* of measles than are convalescent or adult-immune serum, and these are now discredited as therapeutic agents. The prophylactic results reported by Levitas, however, are comparable with those obtained by innumerable observers with convalescent or adult-immune serum. Attenuation attempted in 18 children exposed in their homes, a much more severe test, as S. Karelitz and B. Schick [3] have pointed out, than exposure in a hospital ward, succeeded in 13 cases. In 2 of the children in whom exposure had been "moderate" only the attack failed to occur at all; in 3 there was failure to secure attenuation, attributed to exceptionally intimate exposure and late injection. In another experiment, 12 children, exposed in a hospital ward, were injected with a view to prevention, and no cases of measles resulted. Although none of the children were ambulatory, the nearest bed to the affected child was only about 3 feet from it, and thus if the neighbouring children were in fact susceptible and not already immune, this meagre allowance of space would seem to have provided ample chances of effective exposure. Placental extract is easy to obtain, and the removal of all save the globulin fraction makes it possible to get an extract effective in small dosage. Levitas injected 2 c.cm. for attenuation (1 c.cm. for an infant) and 3 c.cm. (he suggests 3 to 4 c.cm.) for prevention. But the dosage must clearly be tentative at this stage, since there is as yet no standardisation as ordinarily understood. One commercial product is standardised with diphtheria toxin, but since the antitoxic content of placental extract bears no definite relation to the amount of measles protective substance it does not help us much. Further, as McKhann, Green, and Coady [4] have shown, these two principles occur in varying amount in different parts of the extract. There is however a more important objection to placental extract as at present prepared—its liability to produce reactions, both local and general. These have been attributed in part to the presence in the extract of tissue proteins. The properties of placental extract are at the present time the subject of special investigation in this country, and for the moment most workers would agree with the view of the Council on Pharmacy and Chemistry of the American Medical Association [5] that the product is hardly beyond the experimental stage.

THE CHOICE OF A HEARING AID

THERE is at the present time an extensive sale of apparatus to deaf people, a large part of which is caused by the extravagant claims of unscrupulous purveyors. This has resulted in hearing aids falling into some disrepute, in spite of the attention which has been given to them in medical and scientific circles, and the very great benefit that an appropriate instrument may be to many deaf people, and to their friends. The National Institute for the Deaf has issued a pamphlet for the information of the deaf, entitled "The Choice of a Hearing Aid," with the joint approval of its own medical committee and the physiology of hearing committee of the Medical Research Council. The chief causes of deafness, and the types of instrument at present available, are briefly described in non-technical language, with very practical advice on purchase. The deaf are reminded that the National Institute keeps a list of firms who agree to comply with certain canons of commercial etiquette, and who also allow an extended home trial, if 5 per cent. of the value of the instrument be paid when it is not retained at the end of the period. The deaf are advised to read carefully any agreement before signing it, and are warned against certain widely advertised non-electrical "aids," for which the price asked for home trial exceeds the cost of manufacture. The maximum alleviation of deafness can be obtained by the combination of a suitable instrument with good lip-reading. No clinical or experimental evidence has been brought forward to suggest that the continued use of a hearing aid causes any increase in existing deafness; there is thus no scientific basis for a popular fallacy which prevents some deaf people from taking advantage of instrumental help. For the benefit of the deaf, this pamphlet should circulate as widely as the newspapers and books of postage stamps which carry deaf-aid advertisements into the corners of the earth. It can be obtained for threepence from the National Institute for the Deaf, 105, Gower-street, London, W.C.1.

MR. PLOWS

William Henry Plows, a senior clerk in the office of the Examining Board in England of the Royal Colleges of Physicians and Surgeons, died on Monday last at Westminster Hospital after a severe operation at the age of 56. Many of those who have sat for the examinations of the Conjoint Board, or the primary F.R.C.S., will recall the dark short bespectacled figure at the table in the medical clinical room, or standing at the foot of the stairs with the glad news that "you have passed all right." There was, moreover, always a note of real sympathy in his "I am sorry to say that you have failed." Plows was appointed to the clerical staff at the Examination Hall in October, 1895, and would have completed 40 years of loyal and conscientious service next month. To many generations of examiners he will be remembered for his courtesy and imperturbability in all circumstances. Much of the smooth working of the examination system devised by the late Sir Frederic Hallett was due to Plows's grasp of detail and the scrupulous care which characterised all his work.

A DIETETIC LIBERTINE

THE snack bar has become such a popular type of restaurant in recent years that the merits and demerits of frequent rather than heavy meals deserve consideration. H. W. Haggard and L. A. Greenberg [1] have correlated the variation of physical efficiency in factory workers at different periods of the working day with variations in blood-sugar and respiratory quotients, finding that all three are low when work is done after a meagre breakfast or at periods long after a meal. In directing attention to the spacing of meals throughout the 24 hours rather than to the total quantity or quality of foodstuffs consumed they are really suggesting the propriety for normal citizens of a régime long recommended to sufferers from chronic gastric disorders. Dr. Bashford and Dr. Scott suggest (see p. 714) that the part played by irregular meals in the production of peptic ulcer may have been over-rated, but it is easy to believe that the general efficiency of the worker as a machine is promoted by frequent stoking. Dr. Izod Bennett, in a spirited defence of the primitive method of eating to satisfy hunger rather than the peal of the dinner bell, which we print on p. 749, stakes out a claim for freedom to eat what we like when we like. The constant warnings in the last two decades of the dangers of diseases which must follow the increasing artificiality of the people's food have not, he holds, been justified. The manufacturers of margarine for example, have had little difficulty in adding to their product those missing elements which made it inferior to dairy produce as a food, or in supplying a chemical factor of greater value in the treatment of diseases than a natural factor present in food. It is a salutary reminder from one whose professional work has been largely concerned with the disorders of the alimentary canal and has retained an outlook detached enough to poke fun impartially at the food faddist who seeks a cure for every ill in eccentric dietaries, at the new school of gourmets who revolt against standardised food, and at dietitians brave enough to distil from the cauldron of modern theories the essence of a hospital menu.

PATIENT AND DOCTOR

WHAT is the essence of a successful personal relationship between patient and doctor? Sir Henry Brackenbury, in a book reviewed elsewhere in this issue, gives the answer as mutual confidence and coöperation. Few, if any, will disagree with him though opinions may differ as to how that ideal is to be attained, and yet some have certainly deplored the passing of the pomp and circumstance which surrounded the Victorian doctor. The air of mystery made him more impressive and convincing to some patients at least. The modern doctor, on the other hand, who plays golf and slices into the rough may lose prestige thereby, it being inferred perhaps that, just as he foozles his drive, so may he foozle his diagnosis. Far better, it is urged, that the doctor should remain a figure somewhat aloof and mysterious with few social contacts outside his work. Every general practitioner encounters patients who are competitive rather than coöperative, with whom a consultation is a sort of viva-voce examination with the doctor as examinee, who delight in "catching him out" in trivial technical errors, and especially in recovering from their disorders after having disregarded his advice. As Sir Henry Brackenbury says, this competitive spirit is probably born of fear, and it is hard to believe that anything is to be gained by preserving an atmosphere of mystery with such patients since, by so doing, the element of fear may be increased. The genuine unstilted friendship subsisting between so many general practitioners and their patients is surely the greatest incentive to mutual confidence and coöperation. The intelligent patient no longer expects his doctor to be mysterious and infallible. What he does expect (and usually gets) is a reasonable amount of skill and care. Dr. Robert Hutchison said recently that the individual doctor is probably better liked than the profession as a whole, and it is, perhaps, fitting that it should be so.

A SPECIAL lecture by Dr. W. B. Coley, of New York, on the treatment of inoperable malignant tumours with the toxins of erysipelas and *Bacillus prodigiosus*, based on a study of end-results from 1893 to 1934, will be delivered at the Royal College of Surgeons of England on Thursday, Oct. 10th, at 5.30 P.M.

BIRMINGHAM CHILDREN'S HOSPITAL.—An innovation among children's hospitals in this country is the erection at this hospital of a special block of buildings for infants under two. The reason given for the separation of sick babies from older children is that infants ar particularly liable to contract catarrhal infections. Tl aim at this hospital is to have a separate room for e infant, each nurse having charge of not more t two infants.

[1] Diet and Physical Efficiency. By Howard W. Haggard, M.D., and Leon A. Greenberg, Ph.D., of the department of applied physiology in Yale University. London: Humphrey Milford, Oxford University Press. 1935. Pp. 180. 13s. 6d.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXX.—FOREIGN BODIES IN THE AIR AND UPPER FOOD PASSAGES

With few exceptions foreign bodies in the regions under consideration can be removed without injury to the patient and with the prospect of complete cure. The conditions vary greatly with the site of impaction and with the nature of the object.

In the Nose

Children may push pieces of pencil, beads, peas, or other small objects up the nose. There is unilateral obstruction of varying degree associated with rhinitis of increasing severity, leading to suppurative changes. Failure to remove the foreign body results eventually in one-sided blood-stained discharge, sometimes with fœtor, after a period of quiescence. Infection of sinuses may follow, together with signs and symptoms referred to the passage of infected material into the pharynx. Once the object becomes firmly impacted it is not likely to be extruded spontaneously; removal, usually under general anæsthesia, is essential, and will be followed by disappearance of symptoms and signs.

In the Paranasal Sinuses

The most common type of case for discussion under this heading is the result of an unavoidable accident—the slipping of the root of a tooth into the antrum during attempts at removal. Infection of the sinus follows, sometimes acute, but often of a less violent nature. The patient complains of nasal discharge, obstruction, and sometimes fœtor; the cause of the condition is revealed by physical and X ray examination. It is necessary to open the antrum by the canine fossa route, to remove the fragment of tooth, and to make a drainage opening through the inferior meatus of the nose. Treatment of this nature cures the condition, but failure to carry it out leads to all the disabilities and dangers of maxillary sinusitis.

In certain cases pieces of shrapnel, bullets, or the broken end of a cannula are found in the antrum and may cause suppuration. It is, however, possible for an uninfected object to remain quietly in the cavity without causing symptoms.

In the Nasopharynx

The blade of an adenoid curette may break off in the nasopharynx and become impacted there. It will cause inflammatory changes, with subsequent suppuration if not removed, a procedure not fraught with any great difficulty. Vomited material may be projected into the nasopharynx, but is usually ejected spontaneously.

In the Pharynx

Smooth objects do not lodge in this region unless they are of great size, as, for instance, large pieces of meat or fruit. The prognosis in such an instance is extremely bad, as the aperture of the larynx may become obstructed, and attempts at removal with a finger may only serve to push the obstructing object further down. If asphyxia is impending immediate laryngotomy is required to save life, followed by removal of the foreign body under vision.

Small objects of a sharp nature such as bristles, [illegible] or meat bones, pins or needles, may become [illegible]k in a tonsil, in the vallecula, or in the pyriform fossa. In the two first-named positions considerable discomfort is produced, with pain on swallowing; there is seldom danger to life or even severe illness. In the pyriform fossa the position is more serious as perforation of the pharyngeal wall may result. Such an accident is of great danger, as it leads to surgical emphysema and cellulitis, possibly tracking down into the mediastinum, and associated in bad cases with erosion of blood-vessels and even of the common carotid artery.

Irritation of the outer aspect of the larynx leads rapidly to marked swelling of the lax connective tissue of the aryteno-epiglottic folds. Stridor and slight dyspnœa may result, but seldom to a degree sufficient to call for tracheotomy. Suppuration at the site of impaction may, however, lead to the inspiration of infected material, causing septic bronchitis or bronchopneumonia.

In every case the foreign body must be removed with forceps under vision afforded by the use of a tongue depressor, or a laryngeal mirror, or else through a direct laryngoscope. Unless perforation has already occurred all symptoms and signs should disappear rapidly. If the pharyngeal wall is perforated, with resulting external signs, incision through the skin is required. If carried out early and thoroughly this operation should save the patient's life, except in the rare cases where a large artery has been eroded. The seriousness of the complications make it imperative to take careful notice of the patient's complaints and to act with the requisite expedition and thoroughness.

Sometimes a neurosis is set up by a foreign body which has passed on, after temporary impaction, the patient experiencing sensations of pricking and other irritation. If no bone or bristle is found reassurance and some local sedative treatment should lead to disappearance of symptoms.

In the Larynx

Reference has been made to the danger of a large bolus of food lying over the laryngeal aperture or pushed in by blind attempts at extraction. Removal must be rapid to save life, and generally a more useful procedure is the opening of the trachea or larynx. Small objects are seldom arrested in this region. Those which pass through the pharynx usually pass on into the mouth of the œsophagus; if directed into the airway they are likely to be drawn into the trachea and bronchi. Pins and needles, however, may stick in the larynx; they cause temporary cough, followed by a quiescent period, until inflammatory changes cause laryngitis, possibly of a suppurative nature, with perichondritis. Removal through a direct laryngoscope is required, and will be followed by disappearance of symptoms. The proceeding must be carried out with the patient in the Trendelenburg position, as otherwise the dislodged object may pass into the bronchial tree, when the prognosis may become serious.

In the Trachea

Anything which slips through the glottis tends to drop into one or other bronchus and not to stay in the trachea, owing to the considerable size of the latter. Light vegetable objects, such as pieces of nut, may however remain in this part of the airway and will then be blown up and down during inspiration. They do not cause asphyxia by virtue of their size, but give rise to dangerous symptoms because of their irritating nature. Acute tracheitis is produced with abundant secretion and high temperature. Œdema of the glottis may be pronounced and will call for tracheotomy unless bronchoscopic removal is carried out early. Even then dyspnœa may still be distressing, and should be relieved by opening the trachea. The prognosis is grave if this is not done, but is favourable if the correct treatment is followed. The main danger after relief of obstruction at the glottis is from broncho-pneumonia.

In the Bronchi

The prognosis depends on correct diagnosis of the condition and on the possibility of surgical removal. The false hope that the intruding body will be coughed up must not be allowed to prevent bronchoscopic examination, as delay will prejudice the prospects of cure.

There is a vast difference in the prognosis between foreign bodies of vegetable and those of non-vegetable nature. With the former symptoms and signs are early, violent and extremely dangerous, and are caused by the chemical irritation of the intruding substance. As mentioned above, acute tracheo-bronchitis appears, often with œdema of the glottis. The condition is one of urgency and calls for immediate bronchoscopy and removal of the piece of nut, orange or melon pip, or fragment of vegetable. If this is done and if tracheotomy is performed at once should laryngeal obstruction become severe, the prognosis is excellent; if correct treatment is not carried out, owing to lack of skill or opportunity, death is to be expected.

Non-vegetable objects, on the other hand, may lie dormant for months or even years before causing marked symptoms and signs. There is no serious dyspnœa, as the unobstructed lung suffices for respiration. Cough is of temporary duration and only reappears if the object changes its position or if irritation of the bronchial walls leads to inflammatory changes; mucosal swelling and granulations then appear, causing obstruction to the entrance of air and escape of secretions.

Inflammatory changes naturally occur earlier if the foreign body is already infected, as in the case of a tooth, than if it is, for instance, a bead and relatively clean. The patient harbouring an infected foreign body suffers from purulent sputum, sometimes with hæmoptysis, associated with recurrent pyrexial attacks. Lung abscess may ensue and the prolonged suppuration may lead to severe ill-health, with wasting and clubbing of the fingers. Pulmonary tuberculosis must be excluded and a bronchoscopic search then made for the cause of the condition, even in the absence of definite X ray evidence of a foreign body. Pieces of bone or teeth may not show up in radiograms owing to the opacity of collapsed lung.

Except in rare cases, where lung changes are far advanced, removal of the foreign body cures the patient, provided that in the presence of extensive suppuration subsequent bronchoscopic aspiration is carried out. In very advanced cases lobectomy is indicated.

A fine object like a pin may travel down into a distant bronchus and lie dormant for years before causing symptoms. Eventually inflammatory changes occur, and here again the prognosis depends on the question of removal. This requires the use of a double plane fluoroscope. Removal under X ray guidance has considerable dangers unless great care is employed.

In all these cases there is always ample time for all necessary preliminary investigations, including careful radiographic examination. The patient must be transferred to a suitable centre where adequate equipment is available, in the hands of experienced operators. There is no excuse for undue haste or for attempts at removal by those without the requisite skill.

In the Œsophagus

The usual site of impaction is at the crico-pharyngeal fold or, in very young children, rather lower down, at the level of the thoracic inlet. Coins, bones, ordinary pins or safety-pins, and dentures are met with. Smooth objects such as coins are not in themselves likely to lead to a fatal result, although they cause great discomfort and ill-health by reason of partial obstruction to the entrance of food and saliva. A halfpenny may be found, after some three months' sojourn, embedded in granulation tissue, causing dysphagia of considerable but not extreme degree. Careful removal through an œsophageal speculum or œsophagoscope should be followed by a rapid cure; cicatricial stenosis is not likely to follow. It is hasty and ill-considered attempts at blind removal with forceps guided by a finger, or by means of a coin catcher, that lead to danger from injury to the œsophageal walls. An object such as a collar stud, even though smooth, may cause great danger by pressing on the soft posterior wall of the trachea. Early removal gives a good prognosis and tracheotomy should not be necessary. Sharp objects such as bones should be removed as soon as possible, under direct vision, owing to the danger of perforation; contraction of the crico-pharyngeal sphincter may squeeze the object through the hypopharyngeal or œsophageal walls. Early and effective treatment gives an excellent prognosis. Here again attempts at removal by any blind method, as with a probang, are dangerous and unjustifiable. If perforation occurs the outlook is serious, but early external incision and drainage, together with removal of the foreign body, should hold out a good prospect of cure. Laceration of the walls during the removal of a denture fitted with sharp hooks may lead to danger; avoidance of this accident depends on the skill and care of the operator and the suitability of his instruments. Safety is attained, in dealing with cases of a penetrating nature, by removal under general anæsthesia in order to obtain some degree of relaxation of the crico-pharyngeal sphincter.

Most objects which pass the crico-pharyngeal fold and thoracic inlet travel through the œsophagus into the stomach. A bone may, however, pass down the œsophagus and perforate the thoracic segment, with para-œsophageal abscess as a result; the outlook is very bad, but the most hopeful prospect is given by opening the abscess through an œsophagoscope rather than by the external thoracic route.

Summary

No branch of surgery gives such gratifying results as that of foreign bodies. Lack of correct treatment may be followed by prolonged ill-health or death, while removal by suitable methods leads to complete cure. In the majority of cases the prognosis depends considerably on the provision of suitable equipment, used with adequate skill. Hasty and ill-advised attempts at removal afford as great a source of danger as is provided by the foreign body itself.

Surgeon for Diseases of Ear, Nose, and Throat, Kir
College Hospital.

SPECIAL ARTICLES

PLASTER TECHNIQUE IN THE MODERN TREATMENT OF FRACTURES

By K. H. Pridie, M.B. Lond., F.R.C.S. Eng.

SURGICAL REGISTRAR TO THE FRACTURE CLINIC AND ORTHOPÆDIC DEPARTMENT OF THE BRISTOL ROYAL INFIRMARY

(Concluded from p. 685)

The Standard Colles's Plaster

After reduction of the fracture the arm is held by the assistant, who applies countertraction on it, with the elbow bent, whilst the surgeon applies traction on the thumb, so that the hand assumes the position of ulnar deviation, the forearm being fully pronated. A strip of adhesive felt, $\frac{3}{16}$ in. thick by $1\frac{1}{2}$ in. wide, is placed round the arm below the elbow.

THE CAST

1. A dorsal slab is made from a 6 in. by 3 yd. plaster bandage (4 in. for a child). This is made six inches longer than the measurement of the arm from the bend of the elbow to the metacarpal heads (Fig. 13). This slab is laced on the back of the forearm, the extra length being oubled back at the hand to strengthen the wrist portion f the cast (Fig. 14).

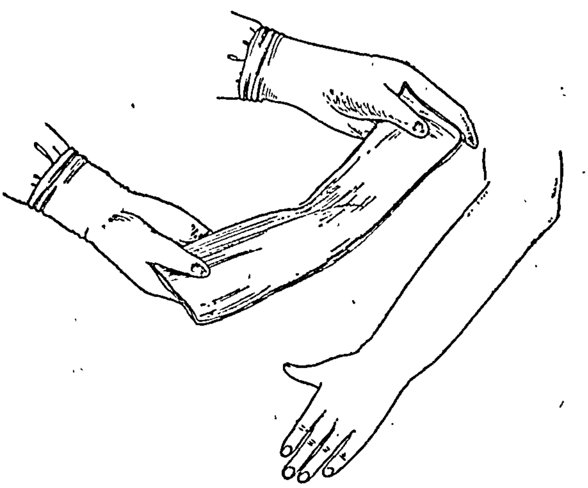

FIG. 13.—Plaster slab applied to the dorsum of the forearm.

The plaster should extend one inch from the olecranon process on the extensor surface of the arm. It should be folded back obliquely (so that it does not press in the antecubital fossa when the arm is flexed) to half an inch behind the metacarpal heads, and the excess turned back over the back of the wrist.

2. The slab is well rubbed on to the hand to exclude air bubbles, and it is fixed to the forearm with a wet gauze bandage, applied from the creases of the wrist to the elbow (Fig. 16).

3. A malleable copper wire band (gauge 12 adults, 16 children) is then made as shown in Fig. 15. This passes round the hand and secures it to the dorsal slab as shown in Figs. 17 and 18.

If the fracture has needed reduction, or if there is much swelling, the plaster should not be completed until the next day, and the patient should be given instructions o keep the hand elevated and not to hang it by his side. nstructions should be given to keep the arm elevated ove the rest of the body at night by laying a pillow the chest and placing the arm thereon. In the day hand should hold on to the coat lapel of the opposite

4. The next day, should the reduction prove to be satisfactory from a second X ray, and should the swelling have subsided, the plaster is completed by the application of a 4 in. by 3 yd. bandage, applied in a circular manner, over the original wet gauze bandage, from the elbow to the creases of the wrist.

This standard Colles's plaster is used in:

1. Colles's fracture after reduction. The cast is worn for 4 weeks.
2. Separated lower radial epiphyses in children. The cast is worn for 3 weeks.
3. Greenstick fractures of the lower end of the radius and ulna in children. The cast is worn for 3–4 weeks.
4. Fractures of the scaphoid. These should be put up in radial deviation and slight dorsiflexion, and kept up until X ray shows union, in 3 months or more.
5. Metacarpal fractures.
6. Difficult finger fractures. In (5) and (6) the plasters are slightly modified.

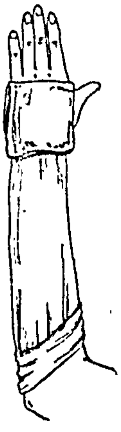

FIG. 14.

Excess length is turned back

Lower Third of Radius and Ulna

These fractures after reduction cannot be adequately fixed by the short forearm cast just described, because pronation and supination must be prevented. The occurrence of *ununited* fractures of the lower end of the ulna is due to the fact that the movement of pronation and supination is commenced too early; the rotation occurs about the fracture site in the ulna—thus preventing union.

U-shaped plaster is used for these casts, which are best fixed in the midway position between supination and pronation.

A 30 in. long slab is made from two 4 in. by 3 yd. plaster bandages. This is placed in a U-shaped manner from the metacarpal heads, along the extensor surface of the forearm, round the elbow, and along the flexor surface of the forearm to the crease of the wrist.

This is fastened to the arm by a wet gauze bandage.

A copper wire band is applied as before to hold the hand.

Full Arm Plaster

A band of adhesive felt is placed round the arm just below the axilla.

1. A plaster slab, 24 inches long, is made from tw 6 in. by 3 yd. plaster bandages (two 4 in. bandages for children). This is placed on the extensor surface of the arm and forearm, which is held in a flexed position just above a right angle and in mid position between pronation and supination (Fig. 19).

2. This is fixed with a wet gauze bandage.

3. A 24 in. slab made from one 4 in. by 3 y bandage is placed to encircle the elbow as shown i Fig. 20.

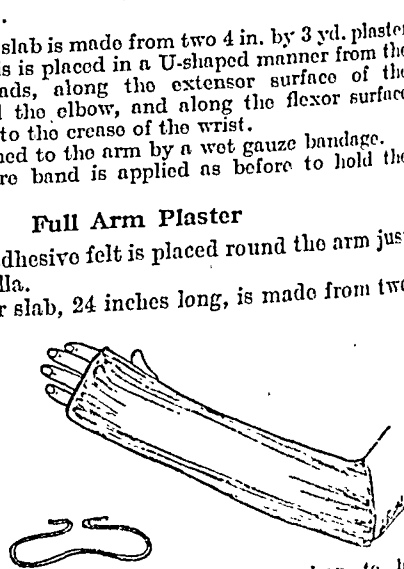

FIG. 15.—Shaped copper wire loop to h attached to plaster slab.

4. A 24 in. slab made from one 4 in. by 3 yd. bandage is placed round the top of the slab.

5. A copper wire is placed round the hand as previously described (Fig. 21).

The full arm plaster is used for (1) fractures of the upper third of the radius and ulna; (2) fractured head of radius, when the segment fractured is not displaced; (3) supracondylar fractures, after swelling has subsided.

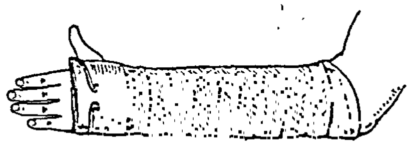

FIG. 16.

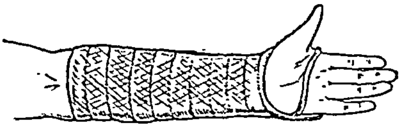

FIG. 17.

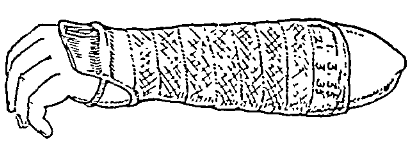

FIG. 18.

Standard Colles's plaster. A wet gauze bandage over the plaster slab secures the wire loop.

Fractures of the Metacarpals

If there is no displacement the standard Colles's cast, extending to the metacarpal heads, will adequately immobilise the fragments and allow the fingers to be used without pain. If, however, there is displacement, so that the bones are overlapping and the knuckle falls back, an extension apparatus must be fixed to the standard Colles's cast, which is the basis of all finger-fracture casts. A U-shaped wire is joined to the dorsal aspect of the dry cast, so that the limbs of the wire extension run parallel to the finger whose metacarpal has been fractured. The end of this U-shaped wire should project 1½ inches beyond the tip of the finger.

A Kirschner wire is then introduced through the pulp of the finger and an extension is made from this to the end of the wire splint.

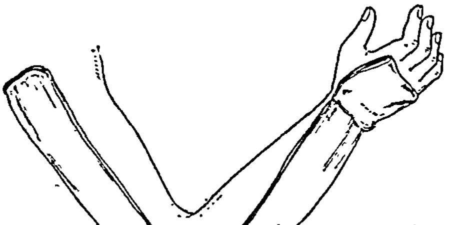

FIG. 19.

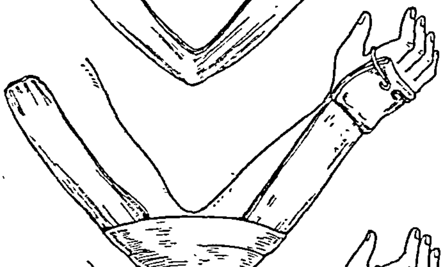

FIG. 20.

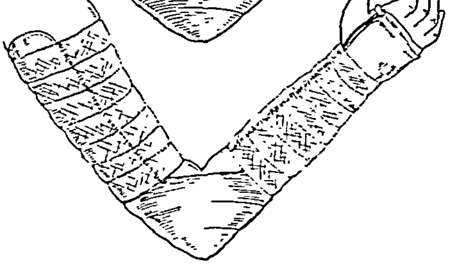

FIG. 21.

Full arm cast, showing wire round hand, and reinforcement of elbow. There are no circular turns of plaster, only of gauze, until swelling has subsided.

Fractures of the Phalanges

The most troublesome of the phalangeal fractures are those through the proximal phalanx. Here the distal fragment tends to be displaced backwards, and these fractures must be treated in flexion. If there is no displacement, the best method of treatment is to place the finger in flexion round a 1½ in. gauze bandage and strap the finger in this position with a strip of elastoplast. The finger is kept in this position for 10–14 days, according to the severity of the fracture.

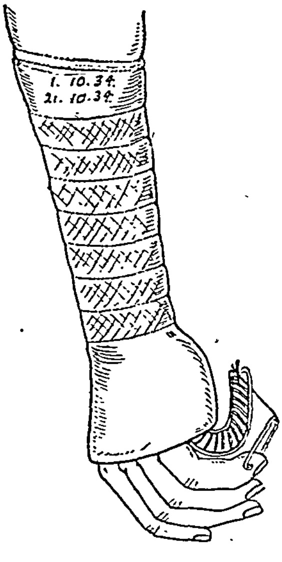

FIG. 22.—Modified Colles's plaster for severe fracture of proximal phalanx with backward displacement.

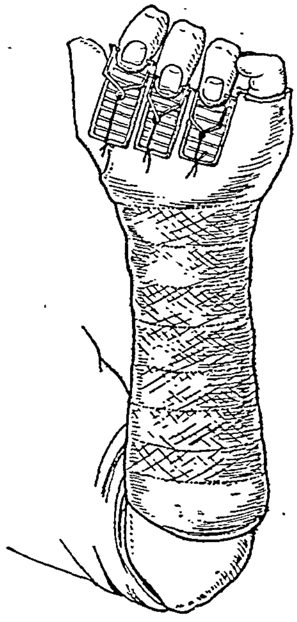

FIG. 23.—Traction applied for multiple phalangeal fracture with displacement.

If there is gross angulation or overlap, traction must be applied to the finger in the flexed position.

The standard Colles's back slab is first applied to the dorsum of the hand and forearm, and fixed with a wet gauze bandage. A ventral slab is then applied extending from just behind the metacarpo-phalangeal joint on the palm to the bend of the elbow.

A Cramer wire splint, ¾ in. wide, which has been bent into a wide U-shape, is padded with adhesive felt on its convex surface, and one end is incorporated in the ventral slab and so fixed that the distal limb of the "U" extends at least 1½ in. beyond the tip of the finger, as shown in Figs. 22, 24 and 25.

A Kirschner wire is then introduced through the pulp of the finger, and extension applied from this to the extremity of the Cramer splint.

Where many phalanges are fractured the splint modified as shown in Figs. 23, 24, and 25. The extension is applied for three weeks to a month, after which active movements are commenced. No physiotherapy should be used until the fracture has united. The same method may be used for the intermediate phalanx. Fractures of the distal phalanx need no special splinting.

For the treatment of torn extensor tendons to terminal phalanges a small slab is made 3 by 2 in. and this is wrapped round the finger, which is kept with the terminal joint hyperextended and the first *two joints flexed. This should be left on for at least* six weeks.

FIG. 24.

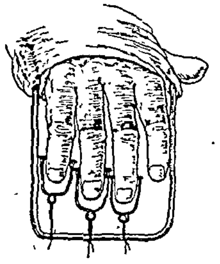

FIG. 25.

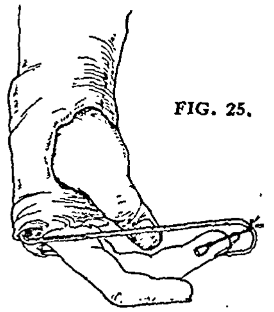

Modification used for compound phalangeal fractures needing traction.

The Skin-Tight Back Splint

This splint is used to immobilise the knee-joint:—

(*a*) In cases of partial fractures of the patella and stellate fractures without displacement (4 weeks).

(*b*) Fractures of the patella after operation enabling the patient to walk with safety after 4 days (4 weeks).

(*c*) Dislocated internal semilunar cartilages after reposition (2 weeks), torn internal or external lateral ligaments or cruciate ligaments (6 weeks).

(*d*) After immobilisation of a tuberculous knee, when the condition is considered quiescent and the patient may commence walking with a guarding plaster (4 weeks or longer).

The method of application is as follows:—

A strip of $\frac{3}{16}$ in. thick adhesive felt, $1\frac{1}{2}$ in. wide, and varying in length according to the circumference of the limb, is placed round the leg four fingers-breadth above the ankle-joint. A second strip is placed obliquely just below the groin.

Four plaster slabs, 33 to 36 in. long, made from two 6 in. by 3 yd. bandages, are placed on the limb—

one on the external aspect
one on the internal aspect
one on the posterior aspect.

The fourth is placed round the top in a circular manner, the remainder is cut off and placed round the bottom. These circular rings prevent the plaster spreading.

The plaster can be completed with a 3 in. wet gauze bandage or, if thought necessary, by two 4 in. by 3 yd. plaster bandages.

Skin-Tight Plaster after Subtrochanteric Osteotomy

The most important part of this operation is the plaster fixation afterwards. This can be simplified if before the operation a standard light below-knee cast is applied and then continued to mid-thigh. A body cast is made with the patient standing. After the operation the two casts are joined together. This only takes a few minutes, and it is easy to determine the right angle of correction.

When the mid-thigh cast has been applied the patient is placed in a standing position on the floor; the pelvis is then made level by adjusting the affected leg. Adhesive felt is applied to the bony prominences in the following manner:—

1. A strip 2 in. wide is applied over the posterior spinous process from the top of the sacrum to the upper limit of the plaster.

2. A triangular piece covers the sacrum from the tip of the coccyx to the posterior superior iliac spines. Two pieces $1\frac{1}{2}$ in. in width are applied to the iliac crests. One piece, 2 by 3 in. (approximate), is applied to the pubic region.

Two 6 in. by 3 yd. plaster bandages are applied over the full extent of the cast in a circular manner, each turn having a pleat taken in it to make it fit the body accurately without tight pulling. Great care is taken to rub the layers as they are being applied. The remainder of the cast is of slabs made from 6 in. by 3 yd.

The first slab is made 36 in. long from two 6 in. by 3 yd. bandages. This is cut in half and one half applied over the iliac crest from the tip of the sacrum posteriorly, over the crest of the ilium, to the pubis in front. The other half is applied to the opposite side in a similar manner.

Two lateral slabs are made from two 6 in. by 3 yd. bandages and placed laterally. One slab is applied posteriorly over the spinous processes from top to bottom. The top of the plaster is finished by one slab. The whole cast is made smooth by two 6 in. by 3 yd. bandages applied in a circular manner.

The edges are then everted and polished with french chalk; when the cast is dry the front is cut out.

After the operation of subtrochanteric osteotomy dressings are applied, and then several turns of wood-wool bandage. The two casts are then joined together by four plaster slabs, 2 ft. long, each made from one 6 in. by 3 yd. bandage. Two bandages, 6 in. wide, applied spirally complete the cast.

This method reduces the time of the operation enormously. It is much easier to judge the required correction and angulation. The cast can be fitted so well that the patient is able to start walking after 3 to 4 weeks —often indeed after 1 week.

THE WALKING SPICA PLASTER

If the leg is placed in the neutral position—i.e., 15° flexion and at right angles to the pelvis—a Bristol iron is applied to the bottom of the plaster as in the standard below-knee cast. If, however, there is much abduction it is advisable to apply a third leg to the cast, made of wood and iron (Fig. 26).

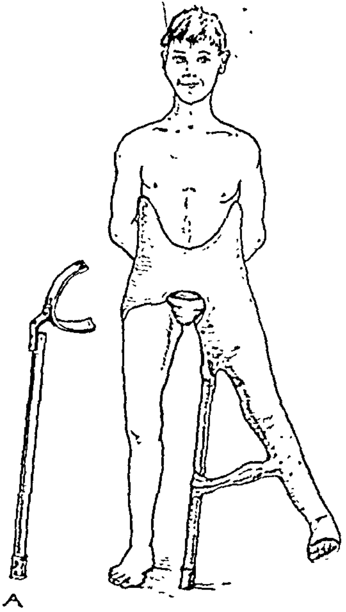

FIG. 26.—Abduction walking plaster.

Directions to Patients

A printed instruction sheet should be given to each patient treated by a plaster cast. The patient should be made to read it and sign the bottom of the card. This card is most important, as it will relieve the surgeon of responsibility where the patient fails to attend or does not carry out the instructions.

INSTRUCTIONS TO OUT-PATIENTS WITH FRACTURES (BROKEN BONES), INJURIES, OR DISEASES TREATED IN A PLASTER-OF-PARIS CAST

Name of patient.......................................

1. For the next........hours you must lie down.

2. During that time, in the case of a fracture of any bone in the upper limbs, have the hand raised so that it is the most elevated part of the body.

In the case of the lower limbs (for example, a broken ankle) raise the foot of the bed and place the plaster cast on a pillow.

You should report to the casualty department if you notice any tightness of the plaster cast, indications of which will be noticed in the fingers and toes as follows:—

(*a*) Marked swelling.

(*b*) Marked blueness.

(*c*) A tight severe pain which is not eased by elevating the limb.

(*d*) Inability to move the fingers or toes. (You should continually move them even while resting.)

(*e*) Numbness or loss of sensation.

Report daily until further notice.

.....................Surgeon-in-Charge.

Patients should be instructed to use the injured limb within the limits of pain, and it should be stressed to them that the more they use the limb the better will be the final result. The patients should not be allowed to use a sling.

SPECIAL INSTRUCTIONS TO FRACTURE CASES TREATED IN PLASTER

A. *Arm Cases*

1. When walking about and not actually using the injured arm you must keep the arm across the chest and grip the lapel of the coat on the opposite side, as long as there is any tendency to swelling. If the injury is below the elbow the arm should be put through the sleeve in about a week's time and the hand used normally.

2. Use the hand and fingers as much as possible for writing, eating, knitting, ordinary household duties, and lifting light objects; this acts as massage to the injured part. If you cannot use the hand there is something wrong and you must see your doctor again.

3. The fingers, elbow, and shoulder should be put through their full range of movement at least 20 times each day. All joints not immobilised by the plaster must be actively exercised.

4. The wire across the palm must be kept well pressed in the middle of the palm. It should not press on the skin at the sides or impede the grip of the hand.

B. *Leg Cases*

1. For the first week following the application of a plaster cast the leg when at rest should be elevated above the rest of the body. Pain due to swelling can be relieved by raising the leg on a box, on which is a pillow. It is advisable for the first week to keep the leg thus elevated in bed.

2. When not actually walking the leg should be raised on a chair. The patient should not stand about on the leg but sit down with it elevated.

After the first week or two the patient can generally disregard these instructions.

3. Patients should walk as much as possible. At first two sticks should be used, then one, which should be held in the opposite hand to the injured limb.

4. When the rubber is worn out on the walking iron it must be replaced.

After-Treatment

Arm.—After an arm cast has been removed the movements of the various joints should be tested. Half range of movements should be obtained almost immediately, and full range after 14 days in many cases. The patient should be instructed to go home and use the limb as much as possible. Until the dry skin has been removed the affected part should be soaked in hot water, and afterwards rubbed with olive oil, twice a day. The case should be seen again after 14 days; in cases where it is considered necessary some form of physiotherapy must be ordered. Approximately 5 per cent. of cases need this.

Leg.—After a leg cast has been removed the limb should be washed with some abrasive soap. After this the movements should be tested. The mid-tarsal joints should be gently manipulated with the hand, as adhesions may have formed in these joints following the longer periods of immobilisation. Some form of supporting bandage must be applied: (*a*) viscopaste where there is no swelling; (*b*) elastoplast if there is swelling. The bandage must be applied to pronate the fore-foot and invert the hind-foot.

(Viscopaste—zinc and gelatin—may, if desired, be hardened with 6 per cent. formalin in spirit.)

PARIS

(FROM OUR OWN CORRESPONDENT)

TUBERCULIN TESTING OF THE FRENCH ARMY

RECENT advances in the study of tuberculosis have done so much to upset certain conceptions with regard to the Pirquet test that it has become necessary to reconsider the whole problem. The director-general of the French Army Medical Service issued in January last a memorandum on tuberculin skin tests in the army. The persons to be tested first are orderlies exposed in the course of their professional duties to infection with tuberculosis; but it may well be that the investigations will be extended to other units. The idea of a Pirquet comb-out of army units in France is not new; in 1934 Debenedetti and Foret carried out Pirquet tests on a regiment stationed in St. Germain-en-Laye, and they found 42 per cent. to be Pirquet-negative. In the *Archives de Médecine et de Pharmacie Militaires* for September, 1935, Prof. M. L. E. Pilod, of the military Val-de-Grâce Hospital, devotes a long article to this subject, discussing the administrative measures that may be desirable as a sequel to the findings he anticipates. Impressed by Heimbeck's studies of Pirquet-positive and Pirquet-negative nurses in Oslo, Prof. Pilod suggests that the orderly found to be Pirquet-negative should without more ado be removed from service on cases of tuberculosis likely to cause a massive infection. While this precaution might well be put into force immediately, there are other possible measures whose application must wait. The most susceptible recruits—i.e., the Pirquet-negative reactors—might perhaps be given special quarters or grouped in special units so that they are exposed as little as possible to undetected infectious cases of tuberculosis. With regard to the vaccination of suc negative reactors with B C G, Prof. Pilod notes th the experience of Brazzaville has shown that e adolescents and adults may benefit from the administration of B C G by the mouth. If the subcutaneous route could be avoided without loss of efficacy, and B C G be given as it is to new-born babies, by the mouth, such preventive treatment of Pirquet-negative recruits might well prove a satisfactory solution of one aspect of the problem.

PIERRE MÉNÉTRIER

Prof. Ménétrier, who died recently following a motor accident, was president of the French Academy of Medicine in 1930. Born in 1859, he first attracted attention in the medical world by his study in 1887 of influenza and pneumonia. Thereafter he published a long series of studies of pathological and bacteriological problems, notably on experimental cancer in mice and on cancer produced by X rays. Ménétrier had to face considerable opposition to his conception of cancer, not as a morbid entity, but as the end of a series of "preparatory pathological states." He was a believer in inflammation as a precursor of cancer, and he looked upon gastritis and ulceration of the stomach as forerunners of malignant disease. It was in his capacity of professor of the history of medicine that Ménétrier had a great following, his wonderful memory and scholarly grasp of his subject being keenly appreciated by his pupils.

BUCHAREST

(FROM OUR OWN CORRESPONDENT)

COMPULSORY IMMUNISATION AGAINST DIPHTHERIA

THE Minister of Public Health has made immunisation against diphtheria compulsory for every child under 10 years of age. The immunisation is carried out with the Ramon antitoxin prepared in a Rumanian serological institute owned by Prof. I. Cantacuzino. The inoculations are performed without charge for professional services or material by official physicians, medical officers of health, district physicians, hospital physicians, or school doctors. Elaborate precautions are being taken to compile records of all children and to prevent evasion of the law. After inoculation the children are sent home from school for three days. After this year no children will be accepted in schools unless they produce evidence of having been inoculated against diphtheria, and no uninoculated children will be admitted to children's summer resorts or convalescent homes unless they are Schick-negative.

SPECIAL EXAMINATIONS FOR VILLAGE DOCTORS

The Minister of Public Sanitation issued an order which prescribes that all doctors who wish to obtain positions as medical officers of health in municipalities, rural districts, and villages must pass an examination in public health, forensic medicine, and toxicology. Examinations are to be held only in Bucharest. Candidates for these positions must also (1) possess a qualification obtained from a Rumanian university, and have been officially recognised as having a right to practise; (2) be a Rumanian citizen; (3) produce a certificate from the proper quarter that he has not been sentenced for any misdemeanour or criminal act; (4) has not had to resign from any official post by reason of any abuse or irregularity; (5) hold no other official or private post, and undertake not to accept one while he fills that for which he is a candidate; and (6) produce a certificate that he has fulfilled his military obligations.

A MEDICINAL SALT DISTRIBUTED BY TOBACCONISTS

In Rumania the sale of both tobacco and salt is the monopoly of the State. This circumstance explains, but does not excuse, the efforts made by the State Monopoly Office to push the sale of a proprietary drug described as natural sea-iodine-salt through its agents, the tobacconists' shops. The leaflets advertising the product state that Palladine, a sea-iodine-salt, when dissolved in baths is recommended for rheumatism, arthritis, anæmia, and general debility, that it allays nervous irritation, and cures uterine and ovarian disease. Emphasis is laid on the fact that the Ministry of Public Health has licensed the sale of this preparation in every tobacconist's shop. To this method of advertisement physicians and pharmacists are taking strong exception.

THE BUCHAREST ANTI-RABIES INSTITUTE

The Babes Anti-rabies Institute, so called after its founder, the late Prof. Victor Babes, has just published a report on the five years, 1929–33. The number of suspicious bites during this period was 36,421, distributed as follows:—

	In towns.	In villages.
Bites from dogs	15,491	10,378
,, ,, cats	1,451	406
,, ,, wolves	5	29
,, ,, horses	36	68
,, ,, swine	33	102
,, ,, *donkeys*	3	10

During the five years under review the number of persons bitten by rabid or suspected animals in Bucharest alone amounted to 9033; the yearly average number of those receiving antirabic treatment was 1806. This figure is alarmingly high in comparison with that of other European capitals—for example, Paris (531), Budapest (438), Vienna (194), Rome (154), Prague (143), or Berlin (36).

In 21 antirabic institutes in other countries 16,328 individuals were treated during 1931, while in the five institutes in Rumania 21,619 received treatment.

ANTISEMITISM AMONG STUDENTS

In his address at the opening of the session Prof. Dr. Gheorghiu, rector magnificus of the scientific faculty of Bucharest University, condemned the attitude during the past year of those medical students who instead of attending to their studies dabbled in nationalistic propaganda. Their antisemitic bias was not shared by their fellow countrymen as a whole. The Rumanian constitution granted citizenship to those of non-Rumanian origin who fulfilled certain conditions, and these citizens could not be prevented from enjoying their lawful right to study at the universities of the country.

"QUALIFIED MASTERS OF DENTISTRY"

The Minister of Public Welfare has issued an order which enacts that all dental technicians, who obtained their qualifications under the law issued in 19[illegible]4, are to use the title "qualified masters of dentistry" in place of "dental technician" on their name-plate and in advertisements, memorandums, and notes. The intention is to make clear that their occupation is regarded as a trade rather than as an art comparable with medicine.

The Goudard prize offered by the French Medical Academy has been won by Dr. Poenaru-Caplescu, professor of internal medicine at the University of Bucharest, for a thesis on the clinical study of appendicitis, the outcome of researches extending over more than twenty years.

THE MEDICAL REGISTER

UNTRACEABLE PRACTITIONERS, 1935

WE have been requested by the authorities of the General Medical Council to publish the following list of registered medical practitioners who had not, when the list was sent to press, replied to letters written to them on behalf of the Council under Section 14 of the Medical Act, 1858, in order to ascertain whether their addresses on the Medical Register are still correct. The date given after each name is the date of original registration; the qualification given is the principal qualification registered by the practitioner. The letters (E), (S), or (I) indicate whether the practitioner was originally registered in England, Scotland, or Ireland; and the expressions (Col) or (For) indicate that the practitioner is registered in the Colonial List or in the Foreign List in the Register. Any practitioner, wherever resident, who finds his or her name in the list should write without delay to the Registrar, General Medical Council, 44, Hallam-street, Portland-place, London, W.1, unless he or she was originally registered in Scotland. Practitioners originally registered in Scotland should write directly to the Registrar of the Branch Council for Scotland, 44, Queen-street, Edinburgh, 2. The name of every practitioner in the list from whom a further communication is not received at a very early date will be omitted from the next issue of the Register in accordance with the provisions of Section 14 of the Act of 1858.

PANEL AND CONTRACT PRACTICE

Changing Doctor: the Problem of Clause 4 (4)

When an insurance committee, after consultation with the panel committee, are satisfied that owing to the continued absence or bodily or mental disability of an insurance practitioner his obligations under the terms of service are not being adequately carried out they may with the consent of the Minister give noticed to the insured persons on his list that the practitioner is no longer in a position to carry out his obligations under the terms of service. So runs Clause 4 (4). In a case of continued absence—for which phrase abandonment of the practice may be substituted—committees usually inform the insured persons that they may select another doctor, assuming of course that the panel committee have been consulted and the Minister has given his consent to Clause 4 (4) being brought into operation. But in a case of physical presence, accompanied by bodily or mental disability, the committee may give notice that the practitioner is no longer in a position to carry out his obligations, but they can neither scatter the practice nor remove the doctor's name from the list. The unfortunate insured person who has received the notice must either continue to obtain treatment from the doctor who, he has been told, is (so to speak) not up to the job or else he must go through the solemn ritual of transferring by consent. This farcical position is doubtless due to the fact that when Clause 4 (4) was drafted insured persons could transfer whenever they liked, in exactly the same way as private patients, but with the advent of Article 16 (1) of the 1928 regulations transfers locally can be effected only if both doctors consent in writing, or alternatively if the consent of the insurance committee has been obtained. So if the patient goes to another doctor—surely the obvious thing to do—he must pay for the privilege until he can secure a transfer which may not become valid for perhaps four months.

An insurance committee in the Midlands being dissatisfied with the position has had it referred to its medical service subcommittee to consider whether an attempt should not be made to secure the removal of the doctor's name from the medical list. Article 34 of the regulations gives the committee power, after an investigation by the medical service subcommittee, if they are of opinion that the continuance on the medical list of the practitioner will be prejudicial to the efficiency of the medical service of the insured, to make representations to that effect to the Minister. But Article 47 clearly provides for representations being made in other ways—and by other persons and bodies—and so cases may well arise in which Clause 4 (4) having been invoked upon the recommendation of a medical benefit subcommittee a representation may be made upon the request of the same subcommittee, or indeed by the insurance committee itself.

This point was brought out in an inquiry held in 1923, where counsel for the respondent submitted a preliminary objection to the inquiry proceeding on the grounds that under the terms of the 1923 Medical Benefit Regulations an insurance committee were *not* competent to bring forward and ask for the hearing before the inquiry committee of a representation owing to the fact, which was afterwards proved in evidence, that no investigation of the matters alleged against him in the representation had taken place before the medical service subcommittee. The inquiry committee over-ruled the objection, holding that Part VI. of the regulations formed, in a sense, a separate code under which the committee could themselves move *de novo* for an inquiry by representation and that the terms of Articles 41 and 42 of those regulations enabled them to proceed without a preliminary investigation or report by the medical service subcommittee. The inquiry committee pointed out that the terms of the regulations lacked clearness in a certain degree on this point in that a declaration of the substantive right of the committee to make a representation of the kind under review was actually found in Article 30—a regulation dealing with investigation by the medical service subcommittee—and that the power to make a representation under Part VI., if that part were rightly viewed as a separate code, was expressed somewhat hypothetically in Article 42.

The respondent in this case applied to the King's Bench division of the High Court to have the decision of the Minister quashed, the principal ground of the application being that the insurance committee had made representations without first directing an investigation by the medical service subcommittee and that the whole of the proceedings were thereby vitiated. But the case was dismissed with costs.

It seems ludicrous that insured persons should be compelled to obtain treatment from, and that insurance committees should have to pay, doctors who have been found by the Minister, the insurance committee, and their professional colleagues on the panel committee, to be unfit to perform their duties.

Costly Certificates

There are probably few insurance doctors who are not asked from time to time to issue certificates of incapacity in respect of patients they have not seen during the previous 24 hours, and possibly there are fewer still who could be certain that they had never done so. A few weeks ago the London medical service subcommittee dealt with two such cases. In the former the doctor had issued weekly certificates to the wife of an insured patient whom he knew was an inmate of a sanatorium, "being under the impression that he was required to supply such certificates even though he had not seen the patient." A para-ph from the subcommittee's report sums up the ition as follows :—

> ule No. 9 of the Medical Certification Rules provides : a practitioner having issued a certificate under the s shall not issue a further certificate without again mining the insured person. The facts of the case were iitted by the practitioner, and it is clear that he, in travention of the rule referred to, issued certificates in ect of the insured person on dates on which he did see him and when, as a matter of fact, the insured son was an inmate of a sanatorium. The practitioner ns to have given the certificates without a due sense esponsibility and to have failed to appreciate that the ited words on the form of certificate issued for the use practitioners contain a statement of fact. It appears us that the practitioner could not have been under illusion when he put his signature to statements ch were not true, namely, that he examined the patient dates when he had not seen him. No question arises to the continued incapacity of the insured person, it is a matter for surprise that a practitioner who has n on the Committee's Medical List for many years should have been so ignorant of the requirements of the Medical Certification Rules.

In the other case, also of a patient suffering from a tuberculous condition, the patient obstinately refused to follow the line of treatment prescribed for him, although the doctor did his best to meet his various predilections, and eventually it became clear that it was useless to make further visits to a patient who would neither take his medicine nor carry out the treatment prescribed for him. But the man was incapacitated and the doctor yielded to the requests of the wife that he should issue certificates hoping throughout that the patient would change his mind and agree to accept appropriate treatment.

Both doctors are likely to be poorer to the extent of £2 as the result of what they no doubt regarded as a technical error, but which the service subcommittee had no option but to treat as a breach of the terms of service.

PUBLIC HEALTH

ie Future of the Health Services in Scotland

[N his presidential address to the congress of the yal Sanitary Association of Scotland, Dr. G. Y. T. Michael, medical officer of health for Paisley, elt upon the need for unravelment of the present nfusion of the health services, and the enrolment the general practitioner in a service the first ject of which would be preventive rather than rative. The general practitioner, he suggested, will quire to put away much of the strongly individual-ic attitude of his predecessors, and become a it in a large team. In an organised service his rk would be easier and certainly more interesting, r he would have at his back all the resources of a mplete medical service, including an adequate ursing service, to assist him in his domiciliary work. ie existing medical services made practically no ovision for a large number of the population who e not in a position to provide for themselves; t one of them was complete, and their adminis-ation was divided among different authorities hich did not coöperate with one another. The me had arrived for a planned national policy, gulating the development of all the health services, a way comparable with the coördination and ganisation of educational effort. It should aim at) a complete environmental health service, and (2) a mplete national medical service, to the benefits of hich every member of the community should have ccess. The distinction was one of convenience; he two branches were essentially interlinked. Dr. IcMichael, discussing the relative merits of a whole-ime salaried service, as compared with a develop-ient of the panel system, came down definitely on he side of the latter, partly because of the personal ond between patient and doctor which free choice reserves, and partly because of the detrimental ffect upon efficiency and the lack of incentive in a vhole-time service, where promotion must depend argely upon seniority. As part of the national rovision for health there should be a maternity cheme managed by the local authorities, affording fficient midwives, competent medical care, and dequate institutional beds to meet the requirements f every expectant mother. Some way must be ound of bringing the voluntary hospitals within the cope of a national service without destroying their individuality and voluntary character. There must be much more active and definite coöperation between the managers of these institutions and local authorities than there has been in the past.

Criticism of the present divisions of local government and proposals for reform have been much bolder in recent years in Scotland than south of the Border. Dr. McMichael, in his address, dwelt upon the necessity for unifying all the medical and health services under one authority. The congress devoted the remainder of the session to discussing the evolution of local government. In a paper on this subject Dr. John Ritchie, medical officer of health for Dumfriesshire, traced the history of local government in Scotland, and pointed out that health authorities of the future must have at their disposal all the resources of modern medical science. Some measure of combination or unification of the present numerous authorities seemed inevitable. Dr. C. W. Sleigh, vice-convener of the county of Aberdeen, described the regional medical scheme at present in operation in Aberdeen, city and county, and the county of Kincardine, which preserved autonomy but ensured the greatest measure of coöperation between the city and the counties. Schemes of this kind, breaking down barriers between the counties, cities, and small burghs, and pooling the hospital and specialist resources of areas, were essential to the development of the medical services. He supported the regional scheme advocated by the Scottish Department of Health, centred on Inverness, Aberdeen, Dundee, Edinburgh, and Glasgow, which has already been described in these columns.[1]

In the discussion of these papers, Bailie Stewart Reid, convener of the public health committee of Glasgow, referred to the new arrangements for domiciliary medical assistance of the poor in that city. It had been decided to abolish all part-time service for this purpose and establish a staff of whole-time practitioners. The day of private practice was past. National health insurance, he was satisfied, had served its day and generation, but was now obsolete. He was convinced that a whole-time service would come, and Glasgow's recent decision was a step toward it. This point of view is not uncommon among the lay members of local authorities, and the reactions of the public in Glasgow and in areas where the open choice system has been adopted will no doubt be studied carefully by the government departments concerned.

Infection in Swimming Baths

Scarlet fever, although maintaining its usual low summer prevalence, has been occurring throughout August at a level rather above expectation. In Chelmsford it has suddenly taken epidemic form at an unusually early period in the season. From an incidence of one to two cases per week during the summer, notifications increased to 9, 223, and 58 in the weeks ended August 24th, August 31st, and Sept. 7th respectively. Figures of this order clearly indicated some special source of infection, which has proved to be a milk-supply, with regard to which particulars are not yet available. Among the steps taken to prevent the further spread of infection, the corporation swimming baths have been closed from Sept. 13th until further notice, on the recommendation of the medical officer of health, Dr. J. C. Sleigh. It would be interesting to know whether there has been definite epidemiological evidence that the disease has actually been spread in this way in Chelmsford. In a fairly exhaustive survey of the literature of the subject[1] written by Dr. J. Alison Glover and other officers of the Ministry of Health in 1929, while the possibility of such an occurrence was mentioned in connexion with small crowded and polluted school baths—and it was recorded that Dr. Griffith had been successful in isolating a hæmolytic streptococcus from one of four samples of bath water submitted for the purpose—it was pointed out that remarkably little had been heard of the transmission of scarlet fever and other nasopharyngeal infections by swimming baths. Since then nothing has happened to call for qualification of this statement.

In times of emergency extraordinary measures must often be taken to allay public alarm. It is clear that the risk of infection is always greater where many young people congregate. Covered swimming baths are often crowded and ill-ventilated. Bathers, becoming chilled and temporarily deprived of the protective secretions of the mucous membranes of their nasopharyngeal passages, may be more than normally susceptible to infection. On general grounds therefore there is justification, during an exceptional epidemic of scarlet fever, for closure of swimming baths belonging to a public body, although other centres of perhaps equal risk cannot so easily be dealt with because of their private ownership.

A Curious Epidemic of Sore-throat

The Northampton coroner inquired on Sept. 9th into the death of a 13-year-old girl, one of a family of six children at the village of Badby, all of whom had been taken ill. The sequence of events was this. The first case was a girl, aged 6, who sickened on August 17th and recovered. The second, a boy aged 8, was taken ill on August 18th and died at home on the 23rd, the cause of death being certified as cardiac failure, septicæmia, streptococcal infection of tonsils and fauces. The third, a girl aged 13 (the subject of the inquest), fell ill on August 19th. A swab taken from the throat proved negative for diphtheria. The child was removed to Northampton General Hospital where she died on August 25th, the cause of death being certified as cardiac failure due to spirochætes of Vincent's angina. The fourth, a boy aged 13 months, taken ill on August 29th, t once removed to the general hospital where throat swabs proved positive for diphtheria and the child was transferred on Sept. 17th to the Staverton Isolation Hospital. The fifth, a boy aged 12, and the sixth, a girl aged 14, were notified on August 31st and Sept. 3rd respectively as suffering from diphtheria and were removed direct to the isolation hospital, where they were both regarded without question as cases of diphtheria. Both are now doing well. A brook running through the village of Badby was blamed for the outbreak, and Dr. A. R. Darley, M.O.H. for the rural district, had the water examined both chemically and bacteriologically; it was stated to be of unusually good quality for a brook water. A septic tank which also came under suspicion has been attended to. Dr. Darley himself regards the probable cause of the outbreak to be a diphtheria carrier; the boy of 12 now in the isolation hospital may prove to have been the carrier. Father, mother, and eldest son, aged 18, in the affected family remain well.

The Keeping of Records

Practitioners may still be heard to complain about the record keeping that the insurance medical system imposes upon them. Yet when they were students they were taught, as clinical clerks, to note the salient facts of a case for future reference. Where patients or problems are handled from time to time by different—and changing—members of a team, accurate recording is the essence of an intelligent and continuous service. Public health workers are thus accustomed to the use of record forms and learn to appreciate their value. Forms are to administration what machinery is to industry; they enable an object to be reached with the minimum of effort. Red tape, often a term of opprobrium, is an effective part of departmental machinery so long as it is used to bind the records and not the minds of its officers.

In one public health department, where a serious effort is made to scrap unnecessary forms periodically and to avoid the needless introduction of new ones, the number of different forms is found, we are told, to total more than 250. These, it should be understood, include various legal notices, intimations to parents, and the like, but the number of forms needed purely for record purposes is large. Many have been devised to suit what appeared to be the requirements of the department and are not based on any model, although in certain services, like that relating to the health of school-children, the returns required by government departments govern the forms of local records. In this connexion a book published by the Commonwealth Fund[1] should be of some help to medical officers in this country, although it is designed to suit American conditions. It discusses the desirability of uniformity of record keeping in health departments, and suggests the most useful forms which might be used for various purposes. Model forms are presented in 79 figures, and the Commonwealth Fund offers permission to health agencies, on application, to use them under its copyright. Public health officers will find in it much useful guidance.

Rebuilding a Leeds Hospital.—Leeds corporation health committee have approved plans for modernising and extending St. James's Hospital at an estimated cost of over £110,000. This should relieve the overcrowding at Leeds General Infirmary. The plans include a pathological block, operating theatres, and a nurses' home.

CORRESPONDENCE

MANDELIC ACID

To the Editor of THE LANCET

SIR,—Since the publication of my preliminary xperiments on the use of mandelic acid in the reatment of urinary infections (THE LANCET, 1935, ., 1032) a more extensive series of cases has been reated with satisfactory results. In the original paper a warning note was added concerning the occurrence of casts in the urine of patients under reatment and since then casts have been found in the urine of a number of other cases. These have been both hyaline and granular in nature and have occasionally been accompanied by albuminuria. On stopping the treatment the casts and albumin have, in every case, promptly disappeared and no evidence of any impairment of renal function has been obtained.

The occurrence of casts in an acid urine, such as is produced by these patients, is of doubtful pathological significance. Recently some evidence has been obtained that the renal irritation responsible for the formation of the casts may be due to the ammonium chloride rather than to the mandelic acid, and it is therefore suggested that the treatment be started with a daily dose of four (instead of eight) grammes of ammonium chloride, which should only be increased if the urine does not become sufficiently acid.

In any case, as previously emphasised, the occurrence of casts or of albumin is an indication that the treatment should be pursued with caution and it should be remembered that the use of ammonium chloride is always inadvisable in the presence of renal failure.

I am, Sir, yours faithfully,
M. L. ROSENHEIM.

Hampstead, N.W., Sept. 21st.

ARTIFICIAL RESPIRATION

To the Editor of THE LANCET

SIR,—I read with interest the leading article in THE LANCET of July 20th based on my article on the best method of manual artificial respiration in the same issue, and I was glad to learn that you think I have made out a good case for preferring Silvester's method to Schäfer's. However, you add that any method which is to be generally adopted should be easily learned and applied by unskilled persons and that in this respect Schäfer's method has the advantage. I grant you this, but before a method can be recommended it must be established that its physiological basis is good, and this is the more essential because it is difficult to draw conclusions from the results of applying any method in ordinary practice. Prof. Henderson has often pointed out that, in cases of so-called apparent death, as a rule it is not known what the condition of the patient was, when he was seen for the first time, because assistance was given by laymen before any doctor was able to determine it. In many cases of apparent death, treated with alleged success, my experience at the Dutch Society for Saving Drowned Persons makes me doubt if the respiration really stopped entirely and if no pulsation was to be felt; in most cases the reflexes were certainly still present, and in such cases various kinds of simple manipulations might have been successful.

My next point is this. Bruns, whom I quoted in my paper, has demonstrated that if in an apparently dead person the reflex irritability is abolished and the respiratory centre does not react to stimuli, no method of artificial respiration can be effective unless it causes blood to flow from the great veins to the right heart and thence through the lungs to the left heart; and Bruns's investigation showed that Silvester's method—and in a lesser degree Howard's method—does this, whereas Schäfer's method does not. It is an established fact that, when a cadaver lying on its back is turned over, the manometer registers a positive blood pressure of 12 cm., which remains fairly constant in spite of strong expiratory pressure; this alone is sufficient to condemn Schäfer's method and other methods in which the apparently dead person is laid on the abdomen. Bruns's experimental investigations were strictly controlled. They have been confirmed by Thiel, and as long as they are not disproved—and Prof. Henderson has not done so—they remain valid.

In my capacity of Secretary-General of the International Association I welcomed the opportunity of publishing an article in your columns, as it seemed to me that some German and Scandinavian publications were not sufficiently known to English and American writers. For collaboration in war-time and at great disasters, it is of international importance to know which method is most to be recommended, and this can only be solved by world-wide collaboration.

Prof. Henderson claims that "no method of manual artificial respiration can do more than induce rhythmic expirations," but he does not support this opinion by argument; and the investigations of Ploman, Liljestrand, Bruns, and others, besides myself, prove the contrary. Prof. Henderson also expresses the opinion that when artificial respiration is being done the inspirations which occur between the forced expirations are due solely to the tonus of the victim's own muscles, and this view is also contrary to the experience of the investigators I have mentioned. Prof. Henderson points out himself in your next issue (page 178) that the muscular tone in an apparently dead person, in whom reflex irritability is abolished, is very low and soon reduced to zero. The muscular tonus of young vigorous students which he mentions is therefore irrelevant.

Elsewhere (Münch. med. Woch., 1935, i., 2) I have set out why the methods of Jellinek and of Holger-Nielsen present no advantage.

I am, Sir, yours faithfully,
Amsterdam, Sept. 12th. C. J. MIJNLIEFF.

*** We have received from our Australian correspondent a letter in which he says: "Dr. Mijnlieff's contention that the Silvester method of resuscitation is preferable to the Schäfer will find few supporters in Australia, where experience in the treatment of drowning is comparatively large and the Schäfer principle is the only one extensively taught. The beaches, where millions of people spend their weekends bathing each year, are patrolled by members of the Surf Life Saving Association of Australia. During the ten years 1925–1935, this association has records of resuscitation by a slight modification of the Schäfer method on 1471 patients; actually no death from drowning occurred on any beach whilst a patrol was present. Rapidity of rescue must be a factor in such success, but much of the credit is undoubtedly due to the method of resuscitatio
The rate of 12 per minute adopted by the associati

was determined by a medical committee after a series of experiments carried out at Sydney University by Prof. H. Whitridge Davies, who found that 15 per minute, the rate previously used, produced considerable over-ventilation. A comparison was also made in these experiments between the Schäfer and the Silvester methods, from which the conclusion was drawn that the Schäfer method was to be preferred."—ED. L.

BACTERIOLOGY OF RHEUMATISM

To the Editor of THE LANCET

SIR,—I am very grateful to Prof. Wilkinson for giving me the clue to Dr. Mantle's paper, and for his kindly personal reference. His letter stirred my subliminal consciousness, and a vague memory of 35 years ago bid me to look up THE LANCET, 1900, ii., 1306, where I found a letter signed by the late Dr. Alexander Paine and myself. I quote a few essential lines.

> "To Dr. Mantle we owe an apology. . . . There can *be no doubt that in 1887 Dr. Mantle* fully recognised the likelihood of rheumatic fever being due to an infection, and that he further carried out some important and laborious investigations in support of his contention."

The nature of these was indicated in that letter, and are given by Prof. Wilkinson.

At the present time, thanks to the paper by Schlesinger, Signy, and Amies (THE LANCET, 1935, i., 1145), upon a possible virus causation, the whole question of the ætiology of rheumatism has been revived, and with energy—perhaps with forgivable energy—I fought for the work and results of those who had pursued the streptococcal causation. It is very right that Dr. Mantle's work of nearly 50 years ago should be recalled, for it was then that some of our great clinicians were from bedside study and post-mortem evidence teaching us that acute rheumatism was probably due to infection.

I am, Sir, yours faithfully,

Bath, Sept. 21st. F. JOHN POYNTON.

PROCTALGIA FUGAX

To the Editor of THE LANCET

SIR,—In Dr. Thaysen's paper (August 3rd) and the full correspondence which it elicited I have seen no reference to epilepsy. I have noted statements in the correspondence which bring some of the cases referred to into line with that which is described below, which I believe is one of epilepsy. I have not myself observed the evidence. Dr. Thaysen wrote of one patient that the pain sometimes waked him, and ceased suddenly; of another, with associated epigastric discomfort, that he became cold and perspired; of another, with similarly associated visceral symptoms, that he fainted. Proctalgia in one of his patients followed coitus and was succeeded by fainting. He quoted two instances in which a parent and child had proctalgia. Dr. Ryle (August 10th) alluded to the incidence of the pain with sleep. Dr. Blyth (August 17th) referred to two cases in which the pain developed soon after masturbation. Dr. McEwan (Sept. 7th) wrote of associated coitus interruptus, and another correspondent referred to proctalgia in brothers, sufficient to cause unconsciousness. Lastly, Dr. Marshall (Sept. 14th) quoted a case in which he finally relieved the pain by amyl nitrite, a remedy for several states, but which the neration of physicians relied on for the abortion tic attacks.

ot suggest that proctalgia fugax is necessarily an epileptic phenomenon, but there seem to be cases in which it is the aura and, at times, the entire epileptic manifestation. It is true that the case I now relate is my only example, but for many years I have known, from a source which I do not recall, of the reality of the rectal visceral epileptic aura.

When I first saw Mrs. B., aged 37, in April last it was rectal pain which worried her; the subsequent attacks of fainting, for which she was sent to me, bothered her much less. She did not know of the possibility of epilepsy. There was no detectable lesion at the local examination on which she insisted, and she shows no evidence otherwise of disease elsewhere. Mental failure was prominent on her father's side. She denied anal coitus. At age 6 she was taught to masturbate, and the habit persisted with regularity for the next ten years. At 10 she had a severe solitary attack of proctalgia, similar to the pain she has now. Because it occurred directly after masturbation she said nothing about it. The menses started at 11; they have continued regularly and are unrelated, in her view, to the pain or to the attacks. At 15½ she fainted on a lawn-tennis court, without clear cause. She had no associated proctalgia, but there was diarrhœa afterwards. At 16 she married, and she has several children. At 25 the proctalgia recurred after *15 years' freedom. It occurred sometimes, but only* sometimes, directly after coitus. A little diarrhœa or the passage of intestinal flatus usually relieved her, but sometimes she fainted. Her husband was also concerned about this time because of attacks which clearly were petit mal. At 31 she had a more severe epileptic attack. Coitus, proctalgia, the fit occurred in rapid sequence.

The attacks of proctalgia, two or three a year, are rather more frequent than the fits. The pain wakes her. On rare occasions it has passed without a fit occurring. She describes it as horrible within the rectum, and sometimes spreading to the womb. It is never at the anal orifice. It makes her draw up her knees and roll about. Sometimes she sweats, and she knows by experience that a faint will then follow. Each attack of pain is similar to the others. There is a definite although inconstant link between coitus and the pain, and on two occasions the pain has waked her from a dream of coitus. The onset when she is not asleep is always abrupt; the pain lasts five or ten minutes, she thinks. If she has a fit she often finds the pain still present on recovery, but fading away. She has no remedy for the pain save the voidance of gas or a small motion. She elects to do this; there is no urgent call. She does this whether she has or does not have a fit, and she thinks that by doing so she has sometimes aborted a fit. Spontaneous disappearance of the pain, without this help, is very rare. She has never had an attack, save the faint at 15, without a preceding rectal pain. In July last she wrote: "I woke this morning at 2 o'clock with the same damned pain. I tried to fight the feeling of faintness, but I went dead off and on coming to felt sick and had the usual flatulence and motion. I went back to bed and must have slept a few minutes, as I woke again at 2.15 feeling very sick but without actual pain, only a wish to pass a motion. I put the chamber on the bed so as to be sick into it, and lay down and again fainted dead off. When I came round I found I had bitten my tongue and had dribbled. I passed a second very loose motion, then went back to bed and slept well."

The epileptic visceral aura, or the epileptic equivalent, which is commonly described is an epigastric sensation. I have seen no other case of rectal or anal aura nor, for that matter, have I ever met rectal crisis in tabes dorsalis. Perineal crisis has come before me once or twice. I am sure that Dr. Howard (August 10th) will not mind a suggestion that he modifies his need to make a test in each case of obscure rectal pain, so as to exclude tabes dorsalis, for we know that tests often fail, at the time they are made, to confirm this correct clinical diagnosis.

Dr. Carter's note (August 17th) interested me.

His patient had pain and other symptoms in a foot which, later on, were associated with rectal pain, although never at the same time. He wrote that a single lesion, causing pain at the two sites, provided an interesting speculative study in neurological localisation.

In February, 1933, I saw a six-year widow aged 44, with one child, who complained that for four months she had pain throughout the second and third toes of the right foot, and in these alone, directly before and during every act of defæcation. It then passed instantly. It was no more than a nuisance to her. Dilatation of the anus, from within or without, did not increase the pain. It occurred whether the fæces were solid or liquid, also with the passage of gas alone and sometimes when the toilet paper made contact. There was no pain or tenderness at or near the rectum, but bi-digital compression of the tissues between the rectum and vagina, at a certain spot, caused instant pain in the two toes. There was no detectable local disease, but she had some slight clinical evidence which suggested insular sclerosis. Her story of the pain, although unusual, was clearly genuine, and I regarded it as referred along the musculo-cutaneous nerve, but from a lesion in the lower sacral plexus.

I do not know why two toes alone were involved. She was treated, at a time the pain was present, by a large epidural injection of warm saline, made through the sacro-coccygeal ligament. The pain was relieved immediately and, save for a slight return six weeks later, with spontaneous recovery, it has never recurred. She remains well. The clinical signs which suggested spinal cord disease are unaltered. The sensory side which, objectively, was healthy remains so.—I am, Sir, yours faithfully,

Harley-street, W., Sept. 21st. HILDRED CARLILL.

T.A.B. VACCINE FOR GONORRHŒA

To the Editor of THE LANCET

SIR,—I should like to bring to the notice of my medical colleagues a form of treatment for gonorrhœa with which I have had excellent results. I am not claiming to introduce something new, as protein-shock therapy has been in vogue for some time. What I do claim is that a fresh infection of gonorrhœa can be cured within two weeks. The gonococcus, as is well known, is a delicate organism, which cannot survive at a temperature of 104° F. and above. My experiments were suggested by the observation that some patients under my charge who developed malaria had a speedier recovery from gonorrhœa than their fellow patients. The method is this:—

On admission the patient is put to bed on a milk diet and given an intravenous injection of 0·25 c.cm. T.A.B. vaccine in 5 c.cm. sterile normal saline. In about an hour he develops a typical malarial attack, the temperature usually rising to 103–105° F. The next day the patient as a rule is quite normal, but some complaint of slight headache may be made. The injections are repeated every third day, the dose of vaccine being increased by 0·25 c.cm. each time. By the third injection the patient is "dry." Three injections usually suffice; I have given four in one case only. In conjunction with these injections local irrigations are given twice daily of a weak (1:10,000) solution of pot. permang. and an alkaline mixture taken internally. On the day of injection no other treatment is given.

Chronic cases also do quite well on this form of treatment, but as there is usually a mixed infection the results are not so striking. The gonococci however disappear after the first or second injection. No after-effects whatever have been noted, and the treatment is quite safe and harmless.

I am, Sir, yours faithfully,

Simla, India, August 29th. A. H. BARTLEY.

THE DRUG HABIT

To the Editor of THE LANCET

SIR,—That hardy annual, the cost of medicines for insured persons, has again flowered. There appears to be no perceptible difference in this year's blooms when these are compared with those of last year, and the year before that, and the year before that, and for years and years and years, as the curate of army concert parties used to say. Surely it is time this plant exhibited some floral variation, even if only by way of a freak bloom. Is it not just possible that what that expert gardener, the late C.M.O. to the Ministry of Health, has gone on all these years regarding as a weed may actually not be a weed at all, but a plant indigenous to the English soil?

When we are told that in Scotland the cost per head of insured persons' medicine is only two-thirds the cost per head in England, let us assume that doctors here and even in Scotland know their business and give their patients not what the patient thinks he or she wants, but what the patient in the doctor's opinion needs. Any other opinion, even if it does emanate from an official of the Ministry of Health, seems to imply that practitioners disregard their obligations to provide necessary treatment. Surely here we have a fact of some importance; roughly, the Scottish population needs two-thirds the medicine the English population of the same size requires. Is there, for one thing, less prolonged illness in Scotland? If a man there takes ill with what may be his last illness, does he die more quickly? If he does, the resistance to infection of the Scottish population is considerably less than that of the English; which would imply that the standard of public health in Scotland is two-thirds that in England; and that increase of resistance due to public health measures is likely to result in increased costs of medicine because with increased resistance on the part of the population illnesses late in life are likely to last longer. Or is it that when a man takes serious ill at the end of his life he is, in the old fashion century ago, "given over" by the physician tious the administration of drugs stopped? This pr small-if readopted in England, would decrease th 1151; of drugs. Again, with a man recovering from ary or illness, it is sometimes wise to continue trea rperal acute of one kind or another for a week or so after h alitis resumed work. If in Scotland, or in those En tery, areas where costs are low, treatment is stopped wera, the man is sent back to work, this suggests the some people may suffer unduly through the cessati of treatment too soon. on 1:

A good deal of information is obviously obtainab from these figures, once they are taken seriously as representing the real requirements of the population. I am happy in possessing a dispensing practice, and from May 1st, 1934, to April 30th, 1935, the average cost of drugs per prescription was 6·62 pence, as compared with the average cost of drugs in prescriptions dispensed by chemists of 3·677 pence for the whole country for 1934. I know the reason for the higher cost here than that in the chief part of the country. In the first place the figure 3·677 pence applies to persons living within a certain distance of a chemist—admittedly the bulk of the population, but people living and working usually under good conditions. Dispensing practices naturally cover populations scattered in small and often old cottage and working exposed to the elements; their dr costs are likely to be heavier, since this popu tion will take ill more severely or more of than one living under better conditions. In this district conditions are distinctly bad, even for the country. The result is a drug-cost per prescription practically twice that for urban populations; to take one example, grs. 10 or 15 of salicylate of soda are needed where I personally should use 7½ in a town.

The explanation which knowledge of actual conditions prompts for these drug figures in my individual practice is borne out by other figures. In an insured population of about 650 there were in the same period 690 panel visits and 2140 panel consultations. Taking 40 per cent. as the number of patients one may expect to see in the year, this would give 690 visits and 2140 consultations to be divided between 260 people. This is 2·65 visits and 8·23 consultations for *each* of these 260 people; or, if it assumed half were sick at home and half came to the surgery, 5·30 visits per person treated at home and 16·46 attendances at the surgery for persons treated there. The last figure is obviously too high; clearly more than 260 insured persons were treated in the year; and these figures, with a low visiting figure and a high consultation figure, show that people are doing what they should, and attending for treatment in the early stages of their illnesses. Treatment then, which means buying drugs for them, certainly lessens the severity of illness and probably lessens its duration, and may keep a man at work. If the man waits till he is too ill to work before seeking treatment the visiting figures go up and the drug figures do not go down, for it will take at least the same amount of drugs to put him right then as it would do to treat him if he seeks treatment when he should. In other words, the drug expenditure prevents a good deal of payment of sickness benefit by the approved societies.

It would be worth while to correlate the figures of sickness benefit payments in the areas where drug costs are low with those in the areas where drug costs are high; but, particular points like this apart, if I can account for my high drug costs by knowing what actual conditions here are, is it not possible t similar explanations may be available for the tions within England? Sometimes "comparable " are not really comparable; and I cannot her to have seen an assessment of the whole insured persons, including sickness benefit nt, for "comparable areas."

I am, Sir, yours faithfully,

C. T. NORRIS.

nea, March. Cambs., Sept. 21st, 1935.

THE DOCTOR AS ADMINISTRATOR

To the Editor of THE LANCET

SIR,—It may be of interest to relate my practical experience in support of the view that the doctor ought to be an administrator, as this is the best way to bring full prosperity and success to any medical institution. I have held the position of not only chief physician but director of the Imperial sanatoriums in Russia. These sanatoriums covered a very big area, more than 1500 acres. There were more than a hundred buildings, including quarters for doctors, male and female nurses, and employees. We had our own church, electric station, water station, post and telegraph office, a big farm, with more than fifty cows, poultry, and so on.

Every department had its own head, but the whole administration was governed by the chief physician. eek there was a committee meeting under hip of the chief physician in his capacity . The committee consisted of the doctors, heads of all departments, secretary, treasurer, book-keeper, architect, and even a priest. Questions on all matters that cropped up were put before the committee and the opinion of everybody concerned was asked. Short discussion followed, and the final decision by the director—i.e., the chief physician—was declared and put in writing. Such matters as canalisation, purchase of a new dynamo, church furniture, plans for the new buildings, all went to the committee for final decision.

During all the years that I acted as assistant physician, chief physician and director, I cannot remember any dissatisfaction or any inefficiency. I have published a book (a copy of which may be found in the British Museum) about the administration of Imperial sanatoriums in Russia in 1913, and the conclusion is that in order to attain a high standard in medical institutions the doctor ought to be an administrator.—I am, Sir, yours faithfully,

London, Sept. 21st. B. A. PEROTT.

VACCINATION ON THE THIRD DAY

To the Editor of THE LANCET

SIR,—Dr. Paterson is very dogmatic about the harmfulness of vaccination and circumcision in the first three weeks of an infant's life. Coming as it does from an authority on children's diseases, this pronouncement is bound to influence profoundly the action of would-be circumcisors and vaccinators, with the result that many infants will be left unvaccinated and uncircumcised until the necessity for one or both has been forgotten by the person interested in the welfare of the infant. One instance is hardly enough evidence to condemn the practice. In my own experience, amounting to nearly 800 cases of circumcision and vaccination performed within ten days of each other in the first three weeks, I have never had cause for regret. The Jewish race could hardly be so well established, and increasing, if early circumcision were detrimental; their method allows an almost bloodless operation to be carried out without anæsthetic or ligatures, an advantage that cannot be enjoyed by infants of riper months. In a similar way, vaccination performed during the first month (taking for granted that only one scarification is made) has the double advantage of a painless procedure and efficient care by the monthly nurse before she leaves the infant to the care of a nanny.

I am, Sir, yours faithfully,

AUBREY GOODWIN.

Queen Anne-street, W., Sept. 19th.

AMOUNT OF HÆMOGLOBIN IN THE BLOOD

To the Editor of THE LANCET

SIR,—The paper from the medical unit at the London Hospital in your issue of Sept. 21st will be most valuable to hæmatologists. I have been for some time endeavouring to find a method of determining the percentage of hæmoglobin that can be used by the general practitioner at the bedside. For this purpose dilution methods are seldom practicable, and it is important that the observations shall be made on fresh blood.

The Dare apparatus has the disadvantage that the graduation of the scale is much too steep. Furthermore, it is originally expensive; replacement of parts is even more so, and they have to be obtained from America. The chief difficulty about the Tallqvist method, which is clinically convenient, lies in the fact that there is a considerable difference in the *tint* of different scales, some being too blue and others too yellow. If however the comparison with the blood made through a piece of green glass, the observer aving his back to the window or a domestic electric ulb and holding the glass close to his eye, the difference in tint is substantially eliminated and the eading can be made, as it should be, by *tone* only.

I have experimented with many shades of glass nd numerous Tallqvist scales. In the result a articular shade of green was selected which answered he purpose, especially in counteracting the aforesaid ifferences between the scales. It is put up in a onvenient frame by the Hospital Contracts Co. 33, Mortimer-street, London, W.1) with a leather over, and can be carried in the waistcoat pocket.

It is not suggested that by this means an absolute etermination of the hæmoglobin content can be ade, but it is sufficiently accurate for comparative bservations in the same patient which are necessary or estimating the value of treatment.

I am, Sir, yours faithfully,
A. KNYVETT GORDON.

Bedford-square, W.C., Sept. 23rd.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdrs. G. H. Hayes to *Pembroke* for R.N.B., mp., and to *Pembroke* for R.M. Infirmary, Chatham; . G. Rainsford to *Pembroke* for R.N.B.; and W. F. eattie to *Victory* for R.N.B.

The following officers qualified at the examination for romotion to surgeon commander held recently: Surg. t.-Comdrs. W. G. C. Fitzpatrick and W. A. Hopkins ualified for accelerated promotion), M. Barton, F. B. uinn, J. J. Cusack, and C. R. Roland.

Surg. Lt. S. Jenkinson promoted to rank of Surg. t.-Comdr.

Surg. Lt. J. W. Oliver to *Pembroke* for R.N. Hospital, t. Yarmouth.

The following have received appointments as surgeon eutenants, R.N., for short service: J. Carlton, London niversity and Guy's Hospital; J. M. Fitzpatrick, Royal ollege of Surgeons, Ireland; A. E. Ginn, Guy's Hospital; . S. Grist, Oxford University and St. Mary's Hospital; . S. Hepburn, Edinburgh University; F. H. Lamb, t. Thomas's Hospital; J. Lees, Cambridge University nd St. Thomas's Hospital; D. Shute, Victoria University f Manchester; H. G. Silvester, University College ospital; D. Simpson, Liverpool University; J. L. S. eele-Perkins, Royal College of Surgeons, Edinburgh; nd W. F. Viret, Leeds University.

ROYAL NAVAL VOLUNTEER RESERVE

W. J. Heely entered as Proby. Surg. Lt. and attached o List 2 of the Severn Division.

ROYAL ARMY MEDICAL CORPS

Lt.-Col. C. E. L. Harding, having attained the age or retirement, is placed on ret. pay.

Maj. S. M. Hattersley, M.C., to be Lt.-Col.

Royal Hospital, Chelsea.—Lt.-Col. H. C. D. Rankin, .B.E., relinquishes the appt. of Physician and Surgeon.

Maj. C. Armstrong, M.B.E., to be Physician and Surgeon.

SUPPLEMENTARY RESERVE OF OFFICERS

Lt. J. Morgan to be Capt.

ARMY DENTAL CORPS

Capt. A. H. Kay is retired under the provisions of Art. 149, Royal Warrant for Pay and Promotion, 1931, receiving a gratuity.

MILITIA

Maj. T. W. E. Elliott retires on attaining the age limit and retains the rank of Maj.

TERRITORIAL ARMY

Capt. W. T. de V. Thomson resigns his commn.

Lt. T. A. S. Kennerley to be Capt.

ROYAL AIR FORCE

Flight Lt. A. E. Vawser to R.A.F. Depôt, Uxbridge.

The following Flying Offrs. are posted to Medical Training Depôt, Halton, on Sept. 2nd, on appointment to Short Service Commissions: A. S. Amsden, H. E. Bellringer, J. P. Carlile, C. M. Carlyle-Gall, W. J. L. Dean, T. J. M. Gregg, R. S. B. McClean, A. B. Marshall, S. R. C. Nelson, R. S. Peill, R. L. Soper, L. N. Trethowan, and J. B. Wallace.

Dental Branch.—Flying Offr. D. P. Boyle to Medical Training Depôt, Halton, on entry into R.A.F., on a non-permanent commission.

INDIAN MEDICAL SERVICE

Capts. to be Majs. (provl.): G. P. F. Bowers, J. S. Riddle, J. E. Gray, S. Smyth, and M. H. Wace.

Capt. J. M. Matthew resigns his commn.

Lt. F. W. Whiteman to be Capt.

Abdul Aziz Khan to be Lt. (temp. commn.).

Col. H. E. Stanger-Leathes, K.H.S., retires.

DEATHS IN THE SERVICES

The death occurred on Sept. 22nd at Harrogate of Surg. Vice-Admiral Sir JOSEPH CHAMBERS, K.C.B. He was born in 1864, the son of Thomas Chambers, J.P., of Bailieborough, Co. Cavan, was educated at Trinity College, Dublin, and qualified M.B., B.Ch. in 1887. He entered the Royal Navy as surgeon in 1889, served in the South African War, and was in charge of several naval hospitals. During the European War he was operating surgeon at the Royal Naval Hospital, Chatham, and was created C.M.G. in 1919. In the following year he was appointed surgeon rear-admiral, in 1922 he was given charge of the Royal Naval Hospital, Plymouth, and in 1923 he succeeded Sir Robert Hill as director-general of the Medical Department of the Navy with the rank of surgeon vice-admiral, retiring in 1927. He received the C.B. (Mil.) in 1923 and was created K.C.B. in 1926, the year after he had been appointed hon. physician to the King. In 1924 he was admitted an Honorary Fellow of the Royal College of Physicians of Ireland and an Honorary M.D. of the University of Dublin. He married in 1908 Irene, daughter of Mr. R. C. Tanner, of Chester.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 14TH, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2162; diphtheria, 1151; enteric fever, 59; acute pneumonia (primary or influenzal), 342; puerperal fever, 42; puerperal pyrexia, 102; cerebro-spinal fever, 11; acute poliomyelitis, 22; polio-encephalitis, 2; encephalitis lethargica, 3; continued fever, 1 (Leeds); dysentery, 18; ophthalmia neonatorum, 70. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Sept. 20th was 2675, which included: Scarlet fever, 838; diphtheria, 960; measles, 35; whooping-cough, 375; puerperal fever, 29 mothers (plus 12 babies); encephalitis lethargica, 271; poliomyelitis, 15. At St. Margaret's Hospital there were 17 babies (plus 4 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox or enteric fever, 6 (0) from measles, 2 (0) from scarlet fever, 13 (1) from whooping-cough, 29 (2) from diphtheria, 63 (8) from diarrhœa and enteritis under two years, and 14 (3) from influenza. The figures in parentheses are those for London itself.

Deaths from diarrhœa and enteritis were distributed over 22 great towns, the highest numbers being Liverpool 18, Sunderland and Birmingham each 5, Gateshead 3, no other great town more than 2. Bristol reported 2 deaths from measles. Leeds and Sheffield each reported 2 deaths from whooping-cough. The fatal cases of diphtheria were distributed over 22 great towns, Birmingham reporting 3, Bradford, Hull, Sunderland, and Norwich each 2.

The number of stillbirths notified during the week wa 272 (corresponding to a rate of 42 per 1000 tot births), including 39 in London.

OBITUARY

WILLIAM DUNCAN, O.B.E., M.B. Glasg.

Dr. Duncan, whose death on Sept. 15th was briefly recorded in our last issue, had been for 15 years attached to the insurance medical service and for two years a senior medical officer in the Ministry of Health. He was born at Cumnoch, Ayrshire, in May, 1872, went to school at Ayr Academy, and took his professional training in Glasgow University, where after winning many academic distinctions he took the M.B., C.M. in 1897, being the prizeman in medicine of his year. In the following year he began general practice at Clay Cross, Derbyshire, and soon established a reputation as a clinician of outstanding ability. But the work of his practice, exacting as it was, formed only one outlet for his fund of energy. He threw himself with enthusiasm into the public affairs of the area, becoming medical officer of health for the Clay Cross urban district, certifying factory surgeon, and a member of the Derbyshire County Council. In these capacities he gained experience in the discharge of public duties which stood him in good stead in later years during his career as an officer of the central government. With his colleagues in South Derbyshire he was popular and influential; his counsel was sought and trusted; and he did much to foster a sense of collective professional responsibility. For some years he was secretary of the Chesterfield division of the British Medical Association, which he represented at the annual meetings, and he was one of the original members of the Derbyshire Insurance Committee. In 1912 he was called to the bar at the Middle Temple, winning the J. G. Powell prize in common law. He was keenly interested in the Territorial Force, which he joined in 1907, and when at the outbreak of the war he was mobilised with the 2–6 Sherwood Foresters his career as a general practitioner came to an end. Throughout the war he served with distinction.

[Photograph by Keith Dannatt

DR. WILLIAM DUNCAN

On leaving the army in 1919 Duncan was decorated O.B.E. and was appointed to the medical staff of the Ministry of Pensions as staff deputy commissioner in the London region. His reserve of energy and ability soon made him a marked man. As one of his superior officers remarked: "It doesn't matter how difficult may be the job you give to Duncan, you can depend upon his doing it as well as it can be done." In 1920 he joined the newly constituted regional medical staff of the Ministry of Health, becoming one of the original regional medical officers. It was evident from the first that he was destined for advancement; in 1928 he was promoted to succeed H J. Neilson as divisional medical officer of the estern division, and in 1933 on the retirement of Sir James Smith Whitaker he became the senior medical officer of the Ministry in charge of general practitioner services. He had hardly entered upon his new duties when he was attacked by the illness to which he ultimately succumbed, and during his last two years of life he was seldom free from pain.

Duncan was a man of exceptional energy and driving force. Difficulties had a way of vanishing before his determined attack. If information had to be got he could be relied upon to get it; if an awkward situation had to be adjusted he could adjust it. He was imbued with an idealism which was probably the chief source of his dynamic qualities. Vigorous, always good tempered, in love with his work, touching life at many points, and gifted with an immense capacity for enjoyment, he was a source of inspiration to many. He faced the long tragedy of his last illness with a smiling serenity, a cheerful acquiescence in the premature ending of his career at the zenith of his powers, that recalled his fellow-countryman, R. L. Stevenson, with whom he had not a little in common. His death has deprived the State of an officer of exceptional capacity for public service, and his colleagues past and present of a much valued friend.

Dr. Duncan was twice married, and leaves two grown-up children by his first wife. In August, 1919, he married Christina Smith, who survives him.

JOHN TRIMBLE ELLIOTT, L.R.C.P. Edin.

THE sudden death of Dr. Elliott, of Smithborough, on Sept. 9th, has caused sorrow throughout the medical profession in Co. Monaghan and other parts of Northern Ireland where he was a well-known figure. The eldest son of the late Rev. John Elliott of Armagh, he studied at the Queen's Colleges of Belfast and Galway, where he had a distinguished career, taking his qualifying diplomas at Edinburgh in 1881. After graduation he held for a year the post of resident surgeon to the Derry Infirmary, and was then appointed dispensary medical officer and M.O.H. to the Kilmore district of Co. Monaghan, a post which he still held at the time of his death. His advice in professional matters was sound and freely given; he was on the council of the Irish Medical Association and for nearly half a century acted as secretary to the county medical association. Some years ago he took an active part in ventilating the question of the standard of the dispensary medical officers in the county; these efforts were successful, and in 1930 his colleagues marked their appreciation of his services by an address and presentation. During fifty-three years of practice in the Kilmore district, Dr. Elliott set an example of the best type of family physician of the old school. He had a kindly personality and a rare

DR. ELLIOTT

of homeliness that brought him into close touch th his patients. Though advanced in years at e time of his death, he was engaged in full practice d had lost little of his vigour and intellect. He himself willing to admit that there were many w and strange things in the practice of medicine; his colleagues felt that these were matters of little practical consequence beside his remarkable breadth of judgment and foresight. Dr. Elliott took no part in politics; his interest was in the social life of the people, who honoured him with the same affection and respect as did his medical colleagues.

MEDICAL NEWS

tilisation of the Laboratory in Medicine

A four-weeks' course of 32 lecture-demonstrations will gin on Nov. 4th in the department of pathology of the itish Postgraduate Medical School provided a sufficient mber of students desire to attend. The class will meet om 3 P.M. to 5.30 P.M. every afternoon, with half an ur's interval for tea at 4, and on Saturday mornings om 10 A.M. to 12 noon. The course will exemplify e utilisation of the laboratory in medicine and will nsist of lecture-demonstrations on clinical bacteriology d immunology by Dr. A. A. Miles, hæmatology and inical pathology by Dr. Janet Vaughan, and chemical thology by Mr. Earl King, D.Sc. The detailed syllabus ll be found in our advertisement columns. Application should be made to the dean at the British Postduate Medical School, Ducane-road, Shepherd's sh, W.12.

versity of Durham College of Medicine

The inaugural address of the winter session will be given Sir George Newman on Thursday, Oct. 10th, at .15 P.M.

rmaceutical Society of Great Britain

On Wednesday, Oct. 2nd, at 3 P.M., Sir Gowland opkins, P.R.S., will give the inaugural address of the ety-fourth session of the school, at the house of the ciety, 17, Bloomsbury-square, London, W.C.

oyal Dental Hospital of London

The prize distribution and conversazione will take lace at this hospital on Friday, Oct. 4th, at 8 P.M., when ir Francis Dyke Acland will preside.

oyal Institute of Public Health

The Harben lectures of this institute will be delivered 28, Portland-place, London, W., on Oct. 14th, 15th, and th at 4 P.M. by Dr. P. Armand-Delille, physician to the pital des Enfants Malades, Paris. He has chosen as subject problems of nutrition and growth, and he will eak in English.

ousing Act, 1935

Lord Balfour of Burleigh will preside at a discussion on Act, which will take place at the Royal Sanitary itute, 90, Buckingham Palace-road, London, S.W., Tuesday, Oct. 8th, at 5.30 P.M. Dr. James Fenton, medical officer of health for Kensington, and Mr. J. S. ler, the housing inspector of Kensington, will open discussion.

Paul's Hospital, London

A post-graduate course in urology will be given at this pital (Endell-street, W.C.) on Wednesdays at 4.30 P.M., Oct. 16th to Nov. 27th. Mr. H. P. Winsbury-White give the first lecture on the ætiology of urinary calculus. er lecturers will include Mr. W. K. Irwin, Mr. Claude ls, Mr. Kenneth Walker, Mr. Stanford Cade, Mr. ocelyn Swan, and Dr. H. N. Webber. The titles of the tures, which are open to all medical practitioners, ill be announced week by week in our Medical Diary.

eurological Research in Leningrad

The Leningrad Institute of Post-graduate Medical Studies has founded a department of pathology and hysiology of the higher centres of the nervous system, edicated to Prof. I. P. Pavlov, who presided at the International Physiological Congress recently held in Moscow. The director of studies will be Dr. M. K. Petrova, one of Pavlov's pupils and collaborators. The purpose of the new department is to enable students to study arious forms of artificially conditioned neurosis by nimal experiment, with a view to applying the knowledge ined to the treatment of human patients.

Colonel George Alexander Troup, T.D., M.D., has been appointed a deputy-lieutenant of the County of Essex.

London Hospital Medical College

On Thursday, Oct. 17th, at 4.15 P.M., Prof. William Bulloch, F.R.S., will deliver the Schorstein lecture on Medical Periodical Literature.

An award of the Liddle triennial prize will shortly be made for the best essay on relations of pregnancy to diseases of the kidney, excluding infections of the renal tract. Further particulars will be found in our advertisement columns.

Preventive Aspects of Infectious Disease in Childhood

Dr. Alison Glover will deliver four lectures on this subject on Oct. 1st, 2nd, 3rd, and 4th at 6 P.M. at Gresham College, Basinghall-street, London, E.C.

Welsh National School of Medicine

Sir George Newman will speak on The New Purpose of Medicine when he delivers the inaugural address of the winter session of this school at the Institute of Physiology, Newport-road, Cardiff, on Tuesday, Oct. 8th at 6 P.M.

Central London Throat, Nose and Ear Hospital

On Friday, Oct. 11th, at 4 P.M., Mr. A. Brown Kelly, consulting surgeon for diseases of throat and nose to the Victoria Infirmary, Glasgow, will deliver the annual address at this hospital on The Œsophagus in Young Children: Some Anatomical and Clinical Observations.

Food Poisoning at Swansea

Investigation into the cause of this outbreak is not yet complete, but a bacillus of salmonella strain has been isolated from various sandwiches eaten by the children and from their excreta. All the children affected are making good progress; there have been no deaths.

Marie Curie Hospital

A small reception was held at this hospital on Tuesday, Sept. 17th, to inaugurate the new diagnostic X ray apparatus which was the gift of Miss Edith Stoney in memory of her sister, Dr. Florence Stoney, a pioneer radiologist.

Newquay Hospital

Since this hospital was opened five years ago a new operating theatre has been built and an X ray plant installed. Now a hostel for nurses has been opened and work is to be begun at once on a further extension which will include waiting-rooms, dispensary, and offices.

Sevenoaks Children's Hospital

This hospital for the treatment of hip disease, on behalf of which no special appeal has been issued for many years, now urgently needs £2000. Mr. E. W. Meyerstein has started the subscription list with a gift of £500.

Kettering General Hospital

A sum of £5000 has been offered to this hospital by Mr. Alan Timpson to form the nucleus of a building fund. It is only 13 months since extensions costing £14,000 were opened, but already further improvements, including a new out-patients' department, are urgently needed.

Manchester Royal Infirmary

Plans for the erection of a four-story building to accommodate 100 paying patients have been passed by Manchester corporation town-planning committee. It is anticipated that fees will be from four to ten guineas a week. The cheapest rates will be for rooms containing four beds, and it is anticipated that more than half the beds will be available at a cost not exceeding six guineas a week. The sum of £100,000 has been raised recently for this hospital.

further found that this variation in efficiency is closely correlated to the concentration of sugar in the blood when this is estimated at regular intervals in such workers, and that it is still more closely correlated with the changes in the respiratory quotient during the same time. When these variations are more closely examined it is found that the efficiency, the respiratory quotient, and the blood-sugar are all at their lowest either in the early morning hours when work is being done after a meagre breakfast, or at periods so long after the mid-day meal that the minor features of hunger are beginning to make their appearance. By increasing the number of meals from three to five, without making any increase in the total amount of food ingested, they were able to increase the physical efficiency of factory workers by a very definite amount as gauged by output. The two additional meals were given in the middle of the morning and the middle of the afternoon, and consisted of milk and cake, it being found that carbohydrate food, as the observations on the respiratory quotient and blood-sugar suggest, was essentially the factor necessary to improve physical efficiency.

What general conclusion is to be drawn from this work? If the reader is the owner of a factory devoted to the mass production of tennis shoes the answer is perhaps easy, but if he follows a different calling it becomes very much more difficult. Perhaps an answer may be supplied by the first and last pages of Haggard and Greenberg's book. On the first page it is written—" breakfast is now generally a light meal; but it is so largely because an elaborate breakfast requires that someone should get up early to prepare it, and service in America now is at a minimum. Again, in most American households, the evening dinner is eaten fairly early; otherwise someone would have to work late to wash dishes." On one of the last pages we read, as to the habits of the subjects under investigation; " all were ignorant of the requirements of nutrition; all ate what appetite or momentary availability dictated. We found one woman who subsisted almost entirely upon cheese sandwiches and candy, another whose diet was at least two-thirds ice-cream sodas, and still another who ate little but bread and jam and coffee."

Perhaps these quotations justify the heading of this article. It is clear that if these American work-people were given a slice of cake and a glass of milk in the middle of the morning and the middle of the afternoon they would produce more tennis shoes, and physicians versed in the difficulties of treating cases of peptic ulcer will immediately recognise that the suggested change of diet would be an immense benefit to any workpeople having a tendency to this disease; but does the community require more tennis shoes, should the healthy man's diet be on the same lines as that of one convalescent from duodenal ulceration, and is mankind happier when housekeeping and domestic life are reduced to the barest possible minimum?

The wild animal, human or other, tends to hunt for long hours or days, and when he has killed his food will eat to repletion and then indulge in a long sleep; whether or not this is a physiological ideal it must surely be remembered when the advisability of a diet of snacks is under consideration. One of the reasons why Amundsen returned from the South Pole when Scott and his companions did not was that the former with his men adopted the wise plan of marching each day until they were tired, and eating at the dictates of hunger, without guidance in either case by the clock. It is no detraction from the merits of the book of Haggard and Greenberg to say that such things must be thought of when drawing conclusions from their work.

Lancashire mental hospitals board is negotiating urchase of about 600 acres of land on the Lathom ate, near Ormskirk, where it is proposed to o new mental hospitals at a cost of about 000.

THE INDIAN FIRE-WALK

A FIRE-WALK demonstration by Kuda Bax c by Mr. Harry Price, the honorary secretary of University of London Council for Psychical Investigation, took place last week in the grounds of a house at Carshalton through the courtesy of Mr. Alex L. Dribbel. Two trenches about 11 ft. long, 6 ft. wide, and 9 in. deep had been dug in which had been kindled a charcoal fire. Seven tons of oak logs, one ton of fire-wood, ten gallons of paraffin, and fifty newspapers were used in preparing the fire. On the top was spread half a ton of forest-burnt oak charcoal. The fire was ignited at 8 A.M. in the morning of Sept. 17th. The walk took place between 3 and 4 P.M. on the same day when intense heat was being given out from the fire. We are indebted to Prof. C. A. Pannett, F.R.C.S., for the following account of the proceedings:

Kuda Bax is the physically slight Indian type. He *claims that his immunity from burning is due to an act of faith, to the influence of his mind over his bodily reactions.* He is temperamental and took a dislike to one pit over which he could not be induced to walk, saying that he felt there was something wrong and unfavourable about it. The explanation of this attitude was perhaps revealed later; he had twice successfully walked over the one pit and had twice walked to the brink of it again to make a third attempt when his courage failed him. He said something had gone out from him and that the physicist who had taken the temperature of the glowing charcoal had desecrated the pit. He did not actually use that word, but said his was a religious act of faith and that it had been rendered impossible by the thrusting of the instrument (a thermocouple) into the burning embers. Up to this time the physicist had occupied himself with the pit from which Kuda Bax had already shown an aversion. When the thermocouple was placed in the fire it registered temperature of 800° C., but when it merely made rapid contacts in imitation of footsteps it only registered, I believe, the temperature of rather warm water. On the other hand two English volunteers certainly blistered their feet in making attempts at the walk.

There appeared to be nothing abnormal about the soles of Kuda Bax's feet. The skin was soft and not at all callosed. It seemed to be very dry, much drier than the feet of the two Englishmen who made attempts to walk on the glowing embers. A skin thermometer showed the temperature of his feet to be 93·2° F. After this they were washed and dried. After an interval of about 20 minutes, during which Kuda Bax loitered about the lawn, he walked the length of the pit which took, I think, four steps. He walked lightly but not with undue haste. He did it twice. Almost immediately after the second attempt (10 seconds perhaps having elapsed) the temperature of the soles of his feet was again taken and found to be 93° F. On inspection no sign burning of the skin could be made out unless it was that certain areas appeared a little whitened, resembling somewhat epidermis which has been sc but not enough to cause blistering. The pigmentation and texture of the skin of the however, made it difficult to be sure even of There was no sign of blistering nor any hype nor did there seem to be any discomfort.

One of the Englishmen, Mr. Digby Moynagh, made an attempt had tried to do the same thing days before. The soles of his feet had nume healing blisters on them. He acquired some at the second attempt. His skin was moister the Indian's and this may have had some influ because afterwards a small piece of charcoal was f stuck to the skin, and on its removal a blister found underneath. It is possible that moisture the charcoal adhere and perhaps prolonged period of contact. The other Englishman, urice Cheepen, who tried the walk was also bli

Dr. Robert Field Library
S. M. S. Medical College

Before Kuda Bax made his attempt, a piece of inc oxide plaster, ⅝ in. square, was stuck to the rch of the sole of his right foot. t the end of the emonstration this piece of plaster showed no signs f burning, except that the fluff from the cotton bric at the cut edge exhibited a very slight amount f scorching. The surface of the ignited charcoal was irregular that contact must have been made with ll parts of the sole.

No other facts were observed.

BIOLOGY AND HUMAN TRENDS

In an article with this title reprinted from the *ournal* of the Washington Academy of Sciences une 15th, 1935) Prof. Raymond Pearl contends that an is "enjoying better health, and individually ives longer than ever before." Of the truth the latter statement there is no doubt, but some ay question the truth of the former.

Prof. Pearl writes enthusiastically of the achieve- ents of medical science. "The last seventy-five ears," he says, "have witnessed more progress in nowledge of disease and its effective treatment and revention than was made in all the time that went fore," and he anticipates that even greater triumphs re in store for us. In regard to unemployment, he fers to the fact that new inventions and increased ansport facilities have enabled a portion only of the rld's population to produce all the essential forms wealth (and more) and to carry on all the business the world, leaving a considerable number of employed, for whom no work can be found. Some these are unemployable by reason of mental or ysical unfitness. "These," he remarks, "are t alive by the rest of society for no realistically onstrable reason other than that they were once ." As to the fit unemployed the author believes t means will be found to reduce their number, ably by the adoption of contraception which with some justice" has been regarded as "the t important biological discovery ever made." does not accept the opinion, generally held, that differential increase of fertility among the least ble members of the community, brought about contraceptive measures, is leading to serious rioration of the race.

The author is a staunch upholder of eugenics; reminds us that at every stage of man's history, before the time of Plato, men have lamented the fference displayed to eugenic ideals. And he etells a distant future when the facilities for easy speedy transport to all parts of the world will to an interbreeding and blending of different es. "In the far off end all mankind will presum- be a rather uniform lot; all looking, thinking, acting pretty much the same way, like sheep" consummation not, one would think, devoutly be wished.

ARGUMENT ABOUT STERILISATION

THREE small books on sterilisation[1] approach subject from widely different points of view. Whitney is the director of the American Eugenics ty, and his book is written in a frankly propa- ist spirit for the interested but ignorant layman. style is conversational and, at times, racy; the es he advocates closely resemble those which favour in this country, except that he wishes to voluntary sterilisation available for habitual nals. The effect of the book is unfortunately by the footnotes of an editor who never s the reader to overlook the occasions upon he differs from the author, and the impression created of a divided opinion upon a controversial

DRUGS AND DOSES

Craig's "Posological Tables" (Edinburgh: E. and S. Livingstone, 2*s*.) and Morton's "Principal Drugs and Their Uses" (London: Faber and Faber Ltd., 2*s*. 6*d*.) have been revised and brought up to date. Craig, which enters on its sixth edition, gives the imperial and metric doses of all official drugs and preparations and many important unofficial ones, together with notes on their action and uses and form of administration. The list is not quite complete. Under tannic acid no mention is made of the use of a solution in the treatment of burns: calamine is stated to be used as an ointment without any indica- tion of its widespread use as a lotion; synonyms of British products—Neokharsivan, Novostab, and

that painting the patches daily with a 1 per cent. solution of iodine in spirit, followed by the application of an ichthyol cream or paste is effective. Alkaline soaps should not be used for washing the face.

ECTHYMA

This is merely a deep form of impetigo in which destruction of the epidermis occurs and an ulcer results; consequently the lesions leave scars after healing. They occur usually on the legs, and circulatory stasis is an important contributory factor, so that they are common in persons with acro-asphyxia, and on varicose legs, where they may be the starting point of chronic varicose ulcers. During the war ecthyma was a very frequent complication of pediculosis, and the *Streptococcus fæcalis* was often the infecting organism (H. MacCormac). The lesions will usually heal under antiseptic applications—e.g., a 1 in 4000 solution of perchloride of mercury applied as compresses after removal of the crusts. In obstinate cases, where as a rule the patient is debilitated, exposure to sunlight or the ultra-violet rays is of value.

INTERTRIGO AND STREPTOCOCCAL FISSURE

With the relapsing lymphangitis to which they predispose, these are the commonest chronic conditions caused by streptococcal infection of the skin. They may, indeed, be regarded as the cutaneous manifestations of chronic streptococcal infection of epithelial structures, which is one of the most difficult of all diseases to cure. As an example, the following case, already described by me in the Guy's Hospital Reports, 1931, lxxxi., 92, may be quoted :—

A lady, aged 28, had scarlet fever at the age of twelve, and from that time had suffered more or less continuously from so-called "eczema" of the ears. She has had five attacks of erysipelas of the face. Before her marriage there was some leucorrhœa, and, since the birth of one of her two children, there has been a thick vaginal discharge. Unless this is checked with a cotton-wool plug she develops "eczema" of her groins. She has also periodically had the "eczema" in the submammary folds. On examination she was found to have (1) typical retro-auricular intertrigo, obviously of streptococcal origin, with chronic meatitis; (2) at the upper angles of the nostrils were the remains of streptococcal fissures, doubtless the portals of entry of infection responsible for her attacks of recurrent erysipelas. The "eczema" of her groins and submammary regions to which she was subject were clearly also streptococcal intertrigo. The vaginal discharge was found by Mr. F. Cook to be due to a chronic cervical erosion. Prof. Eyre recovered a *Streptococcus pyogenes longus* with other organisms from the retro-auricular intertrigo and the nasal fissures.

This case illustrates very well the persistence over a period of sixteen years of a streptococcal infection of the skin dating from an attack of scarlet fever. The patient was very lucky in that her repeated attacks of erysipelas, arising from neglected nasal fissures, did not lead to permanent blockage of the lymphatics of the malar regions and eyelids. The patient's sister was also under my care for chronic retro-auricular intertrigo.

The prognosis as regards cutaneous lesions in chronic streptococcal infection is more favourable than where the mucous membranes are involved, but even so relapse is common, particularly in those who are compelled to live sedentary indoor lives. As has already been indicated, I believe that diet and environment are important factors, and I am convinced of the value of vaccine therapy, if it is employed judiciously and for a sufficient length of time. An important point is that the local treatment of intertrigo and fissure must be continued until a normal epithelium has been re-established, for otherwise relapse is certain.

ACUTE ERYSIPELAS

Severe cases of erysipelas, ending sometimes fatally, are less common than formerly, and I do not think that this is entirely due to more effective treatment. Possibly the diminution of chronic alcoholism may be partly responsible. A. Rendle Short (Index of Prognosis, 1915) states that the mortality in 875 cases at St. Bartholomew's Hospital, collected several years ago, was 3·5 per cent. In cases in which there was an accompanying cellulitis it was much higher—11 per cent. in 889 cases. W. H. Guy (Jour. Cut. Dis., 1919, xxxvii., 399), D. Symmers and K. M. Lewis (Jour. Amer. Med. Assoc., 1927, lxxxix., 880) and others have emphasised the therapeutic value of streptococcal antitoxin. H. Semon has recorded the remarkable effect of intramuscular injections of aolan in a case in which a fatal result had been anticipated, and in recent years I have employed this method of treatment in several cases of varying severity with uniformly good results. In the absence of unfavourable conditions, such as alcoholism, diabetes, chronic renal disease, long-standing malnutrition, and cachexia, the prognosis in acute erysipelas may be regarded as very favourable.

RECURRENT STREPTOCOCCAL LYMPHANGITIS (RELAPSING ERYSIPELAS)

This is one of the most important and serious complications of chronic streptococcal infection of the skin, because the repeated invasion of the lymphatics may eventually cause their blockage, giving rise to persistent elephantiasis and consequent disfigurement. The streptococcal fissure is the usual portal of entry to the lymphatics. When these occur between the toes, they are usually secondary to epidermophytosis. They may cause recurrent attacks of lymphangitis of the feet, ankles, and legs, the origin of which is often overlooked. I have recently seen two cases in which permanent blockage of the lymphatics with the production of elephantiasis had occurred from this cause, and in both the interdigital fissures and mycotic infection had been disregarded. The importance of thorough treatment of interdigital epidermophytosis is thus manifest, since it may in this way be indirectly responsible for permanent, though partial, disablement.

Recurrent lymphangitis, however, most frequently occurs on the face, giving rise all too often to persistent elephantiasis ("solid œdema" of Hutchinson). This condition has long been recognised under various terms—e.g., erysipelas perstans faciei (Kaposi), erythema perstans faciei (Kreibich), lymphangitis faciei (Mackenzie). The parts affected are usually the malar regions and the eyelids, and exposure to cold is certainly a factor predisposing to the attacks. In the great majority, if not in all cases, the portals of entry for infection of the facial lymphatics in this area are fissures at the angles of the nostrils. I am aware that cases have been recorded in which it was stated that no such fissures were apparent, but I believe that a careful examination with a strong light of the nasal vestibules at the time of the attacks will almost invariably reveal them, and, as a rule, they are seen even in the intervals. They are often associated with impetiginous anterior rhinitis, chronic nasal and nasopharyngeal catarrh, and sometimes with sinusitis. Their treatment is of paramount importance, since a repetition of the attacks of lymphangitis will in time inevitably lead to lymphatic blockage and permanent disfigurement. Less commonly, relapsing erysipelas involves the ear, neck, and side of the face, and is then due to chronic or recurrent fissures below the lobe of the ear, or in the retro-auricular space. Involvement of the lips may occur from chronic fissures at the labial commissures (*perlèche*), or in the centres of the vermilion borders.

The prognosis is in these cases good, providing that persistent blockage of the lymphatics has not already occurred. Thorough treatment of the fissures with a silver nitrate paint and a mercurial ointment or paste should be carried out until a normal epidermis has re-formed. In obstinate cases a few fractional doses of X rays are sometimes helpful. Even when blockage has not yet occurred, local treatment may well be combined with injections of an autogenous or a mixed stock streptococcal vaccine, which in my opinion give better results if made intradermally. In my experience these cases are extremely sensitive to the vaccine, and even very small doses are likely to produce a local necrosis at the site of the intradermal injections and a flare up of the lymphangitis.

When persistent lymphatic œdema is already established the prognosis is much less favourable. In some cases, however, I have had good results with intradermal injections of streptococcal vaccine, given over a long period in gradually increasing doses. In America injections of *Streptococcus erysipelatis* toxin have been favourably reported upon in these cases, and G. C. Andrews (Diseases of the Skin, Philadelphia, 1930) states that they are "a specific method for the prevention of recurrences and the reduction of persistent lymphœdema in cases of chronic recurrent erysipelas."

H. W. BARBER, M.B., F.R.C.P.,
Physician for Diseases of the Skin, Guy's Hospital.

SPECIAL ARTICLES

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS

THE twenty-first annual conference of this association was held at Southport from June 27th to 29th, under the chairmanship of Sir ROBERT PHILIP, the general subject for discussion being the

Responsibility of the Nation towards the Child in Respect of Tuberculosis

Dr. G. LISSANT COX (Lancashire) said it might readily be supposed that the sub-standard child, as compared with the normal child, was more likely to be infected by, and die of, tuberculosis either as a child or later as an adult. This did not appear to be so, as a special survey made in Lancashire had shown. But since infection might lead to disease, it was of the greatest importance to safeguard the child. It was known that under certain conditions there was a very high non-pulmonary tuberculosis death-rate in young children subject to infection from mother or father. Further, in an investigation into "contacts," it had been shown that at least 15 per cent. of known cases of pulmonary tuberculosis gave rise to secondary cases, in spite of modern antituberculosis measures, the average interval between the discovery of primary and secondary cases being 3½ years. The three factors on which methods of prevention were based were isolation, immunisation, and environment. In Lancashire they had taken as their basic principle the words: find, isolate, educate, and treat the *adult positive case.* They had always concentrated on the adult positive case, believing that this safeguarded the child. Dr. Cox briefly described the various methods of isolation—the Grancher system, hospital or sanatorium isolation, or village settlements for the whole family. With regard to the provision of hospital isolation, the number of beds which should be available throughout the country was one for every death from tuberculosis. At present only a very small minority of tuberculosis workers in this country advocated inoculations for immunisation, and the speaker thought that the present state of knowledge did not warrant a large or routine use of this method of safeguarding children against infection. The principle of environment was at least as important as that of isolation. It had been shown conclusively that a higher standard of living and of housing was a direct safeguard against infection, and to this factor was largely due the great diminution which had already occurred in the incidence and mortality of tuberculosis.

Dr. M. SKOKOWSKA-RUDOLF (Warsaw) pointed out that the two peaks of tuberculosis mortality in childhood were in the first year of life (decreasing during the 3–7-year period), and in adolescence. Preventive efforts should be directed chiefly towards these two periods. Poland had adopted Calmette's system of B C G vaccination, while among other suggested provisions for the protection of tuberculous children and those in danger of infection were the following: (1) to instal for every 100,000 of the population three pairs of beds for expectant mothers (suffering from tuberculosis) and their infants, in order to allow of proper B C G vaccination and instruction of the mothers in nursing their babies; (2) to instal 12 beds for every 100,000 of the population for inoculated children; (3) to provide a minimum of 5 hospital beds for tuberculous children of pre-school age (3–7 years) for every 100,000 of the population; (4) to provide 10 sanatorium beds for every 100,000 of the population; (5) to create forest school preventoriums for children of school age, taking as standard 40 beds for every 100,000 of the population; and (6) to instal as auxiliary establishments "half sanatoria" (day and night sanatoria). These institutions were already doing good service in the big cities of Poland, children from tuberculous families spending the greater part of the day in them.

BOVINE TUBERCULOSIS

Major A. B. MATTINSON, F.R.C.V.S., spoke particularly on infection through the milk-supply. Assuming as approximately accurate the statements that any cow giving tuberculous milk to-day would be dead within a year, that any cow affected with tuberculosis to-day would be dead in five years, and that almost every cow which would be giving milk in 1940 was either unborn or was at present free from tuberculosis, certain lines of progress were indicated, including an overhaul or at least a tightening up of the various Acts and Orders. Major Mattinson outlined many ways in which the incidence of clinical bovine tuberculosis might be brought under control, urging adequate veterinary supervision of dairy herds with the object of reducing clinical—and not merely mammary—tuberculosis at its earliest manifestation.

Dr. NATHAN RAW (London) said that while no animal could be given an immunity to a lethal dose of virulent bacilli, it could be given an immunity sufficient to resist a mild form of infection, which was the usual method by which the animal was attacked. The immunisation of calves was simple, the method Dr. Raw adopted being the injection of cultures of human bacilli which were non-pathogenic and avirulent. The vaccine was injected when the calf was a week old, and again at the end of two weeks, and very satisfactory results had been obtained.

Dr. R. VEITCH CLARK (Manchester) said that the elimination of bovine tuberculous infection was merely a question of money and work, and neither of these was beyond the capacities of this nation. At present there were about 2000 deaths each year from this cause in England and Wales, and three-fifths of them were in persons under fifteen years of age. Tuberculous infection of cattle varied in incidence, but on the average 6 per cent. of the milk in England and Wales was infected. In Manchester during the past thirty-four years the average was 11 per cent., and during the past five years it had varied between 11 to 16. For years the country had submitted to the sale of a food known to be producing an enormous bulk of disease, and it was time that active steps were taken against the continued menace. Of the graded varieties pasteurised milk was the only one which from the point of view of protection against tuberculosis had given good results both in quality and in quantity. This form of milk-supply was the only protection at present available to the public against the conveyance of tuberculosis; it removed this source of infection and afforded a degree of protection which would almost entirely eliminate the disease. It was significant, Dr. Veitch Clark added, that the Ministry of Agriculture in its scheme for the registration of tubercle-free herds required that no calf should be fed except with milk from a tubercle-free cow or with milk which had been pasteurised or sterilised. If this was necessary for calves, surely it was infinitely more necessary for children.

Dr. M. CHRISTIANSEN (Copenhagen) said that Denmark had been the first country to organise a rational eradication of tuberculosis in cattle. As early as 1892 Prof. Bernhard Bang set out his method for combating this disease, since which time it had been adopted with or without modification in many other countries. As a result of it tuberculosis in cattle had now been eradicated completely on several Danish islands, the herds comprising a total of about 75,000 cows. Complete eradication of cattle tuberculosis had also been accomplished in several dairy districts of the larger islands. A sanitary regulation laid down that from the year 1938, at latest, all milk distributed in Copenhagen must come from healthy tuberculin-tested stocks, and several other provincial towns in Denmark had already carried through a similar ordinance concerning the milk distributed for sale.

B C G VACCINATION

Dr. E. RIST (Paris), after describing the experiments carried out by Calmette and Guérin which culminated in the strain of tubercle bacillus known as B C G, said that there was now practical unanimity of opinion as to the harmlessness of B C G administration to infants. The special expert committee appointed by the Public Health Committee of the League of Nations to examine the possibility of spontaneous variations of B C G resulting in its transformation into a virulent strain, unanimously concluded that this had never occurred experimentally, nor had a single instance of its spontaneous occurrence ever been reported. The essential question, however, was whether B C G really did protect the child against virulent infection. Objections, for the most part justified, had been raised against Calmette's first statistics; but later work, notably that of Arvid Wallgren, of Göteborg, Sweden, showed very conclusively that B C G vaccination was really able to protect previously uninfected children against virulent infection. The immunity conferred, however, was probably neither absolute nor lasting, and therefore it was important that the children should be exposed to virulent infection when the vaccinal immunity was at its height. The result of this would be to transform the relative and short-lived artificial immunity produced by vaccination into a stronger and more lasting natural immunity. Calmette and Guérin's discovery must be regarded as the first successful attempt at specific prevention of tuberculous infection in human beings.

Dr. K. NEVILLE IRVINE (London) said that, apart from the Lübeck disaster, of the fatal cases which had been reported—about 30 in number—none had been proved beyond reasonable doubt to be due to the vaccine. As to the effectiveness of B C G, only two out of more than a hundred reports from clinics all over the world found it to be inactive; all the remainder showed varying degrees of protection. While B C G was not perfect, it was worth considering that the vaccine had been proved safe for a million and a half children, that it reduced the morbidity-rate from tuberculosis in children by at least half; that already it was being used in nearly every European country except Great Britain; that it was safe in even inexperienced hands; and that it was not costly.

Sir ROBERT PHILIP, the chairman, said it would be a mistake to suppose that no work at all on B C G had been done in this country; a great many observations had in fact been carried out behind the scenes. It was clear that the vaccine was efficacious to a considerable degree, but it had not yet been settled how far the effect was permanent.

EARLY EVIDENCE OF DISEASE

Dr. CHARLES CAMERON (East Lothian) said that although infection and disease were not synonymous, yet infection must precede tuberculous disease. The day might come when the use of the various cleavage products of tuberculin would make it possible to discriminate between harmless infection and active disease, but in the meantime fuller use must be made of the information provided by the tuberculin test. The test should never be omitted in the elucidation of obscure symptoms in childhood, and a positive tuberculin reaction was a signal for the use of measures for raising the child's natural resistance, including the therapeutic use of tuberculin.

Dr. N. TATTERSALL (Leeds) said he did not look on a positive skin test as an indication for treatment. The question was: Were there any steps to be taken or tests to be applied to discover which infected child was in danger from his infection? In many cases this was not possible; seed time and harvest lay too far apart—perhaps twenty, thirty, or forty years. But he thought there was a not inconsiderable number of children in whom could be recognised a stage of infection, the unstable or significant lesion, which was an imminent danger to them, particularly in adolescence. A much wider application of X rays would bring to light far more of these unsuspected cases than was at present realised. Dr. Tattersall suggested that the time had come when every child should have a tuberculin test on entering and on leaving school life, and once in the middle years, and that every child—not the positive reactors only—should be radiographed at the same three periods. Close coöperation between the tuberculosis dispensary and the school authorities would be essential. Among other measures for detecting early infection might be a wider use of the sedimentation and other blood tests. An application of these methods to children might help to show the dividing line between infection and disease in childhood, without which a knowledge of "infection" only was of comparatively little practical value.

Dr. L. S. T. **Burrell** (London) pointed out the necessity for finding terms to distinguish between persons infected with tuberculosis with and those without clinical disease. The term "pre-tuberculous" was a bad one, but if used at all, it should be applied only to those with a negative tuberculin test. Those with a positive test were already infected, and in such persons certain signs or symptoms might develop which experience showed would render the individual liable to become consumptive, even when clinical and radiological examination revealed no active disease. The importance of examining children was chiefly to detect this stage of latent tuberculosis. It was a matter of the greatest difficulty to determine whether or not a child had a lesion which might develop into active disease, and which therefore needed treatment. The child might be in danger either because it already had some lesion, or because it was in contact with infection. Examination should therefore have the double object of discovering any lesion present and of determining whether the child was in sufficiently close contact with infection to render it liable to develop tuberculosis. The second of these objects was by far the more important since it aimed at prevention rather than cure. It was not only easy to overlook a tuberculous lesion which was present, but it was even more easy to imagine one when the child was weakly or undernourished. Weakly children did need treatment, and since to treat them in a sanatorium or preventorium was as good as any other method, it mattered little whether or not their disability was due to tuberculosis or not. What did matter was that the strong children should not be neglected, because they were equally susceptible to tuberculosis. Adults rather than children should be examined in an infected household, to discover a possible source of infection; and any child, robust or delicate, was in grave danger of being infected or reinfected if he remained in contact with a case of open tuberculosis.

Dr. H. **Midgley Turner** (Sheffield) said that children who attended for periodic examination at a tuberculosis dispensary could be divided broadly into three classes: (1) notified cases of tuberculosis; (2) infected children without symptoms or signs of active disease, who were still exposed to known sources of infection; (3) children not yet infected, but exposed to a known source of infection. The purpose of examination in the first group was to assess the general health, to ascertain that there was no evidence of toxic absorption, to examine carefully for any change in the local signs of disease in the system known to be infected, and to note whether spread to other lymphatic systems had occurred. In the second group the object was to seek any subjective or objective evidence that the child was being adversely affected by the tuberculous infection, and, if so, to localise and treat the lesion. In group 3, examination was directed towards observing the reactions of the child when infection occurred, and taking steps where necessary to begin treatment. The aim, therefore, of systematic examination of children was to detect the earliest evidence of clinical disease, remembering that the examination must be concentrated mainly on the child's lymphatic system. Sputum-positive pulmonary tuberculosis in the child was relatively uncommon.

OPEN-AIR SCHOOLS

Dr. C. J. **Thomas** and Dr. **Noel Bardswell** (London County Council) described the growth of the open-air movement in schools in London, and the remarkable improvement, physical and mental, in the children attending such schools. Two principles of exceptional importance in this work were, first, the necessity for constant vigilance to see that in all ways complete sanatorium conditions were preserved, and insidious attempts to introduce heating firmly resisted; and, secondly, the necessity for an ample supply of good nourishing food.

Dr. **Ralph Williams** (Board of Education) said that the day and residential open-air school had definite places in the prevention of tuberculosis, providing treatment for the child in the early and non-infectious stages of the disease, and for the delicate contact. Such schools were centres for the teaching of hygiene and were a useful means of educating the public. The design of the open-air school had also had a valuable effect on the planning of ordinary school buildings.

Councillor **Stewart Reid** (Glasgow) and Alderman T. **Hamblett** (St. Helens) also discussed the principles upon which open-air schools were designed, and urged the adoption of such principles by ordinary schools—a measure which they thought would go a long way towards eradicating tuberculosis, not only in childhood but also in later life. School feeding was also probably one of the most important functions they had to perform.

NATIONAL CONFERENCE ON MATERNITY AND CHILD WELFARE

THE CHILD FROM TWO TO FIVE

The first day's sessions of this conference[1] were held in the London County Hall, Westminster, on July 1st, under the chairmanship of Mr. **Somerville Hastings** (chairman of the hospitals and medical services committee, L.C.C.). After a short opening speech by Lord **Snell** (chairman of the L.C.C.), the presidential address was delivered by Sir **Kingsley Wood**, Minister of Health. He said that satisfaction with the steady progress made in child welfare must be tempered by our failure to improve the toll of maternal mortality. There had been a consistent reduction in deaths, among infants and among children between the ages of one and five years, largely brought about by the work of health visitors in the homes, and that of infant welfare centres. There had been a gradual decline in the percentage of children entering school in need of medical treatment. Few areas now failed to provide the essential features of a progressive child welfare service, but there was evidence than an inadequate number of toddlers were benefiting by it. The remedy lay in instruction of the public and arousing of public interest. It was impossible to emphasise too strongly the importance of better housing; if we could eliminate the majority of slums within the next five years, our generation would have given one of the greatest contributions to the health of the people ever made. The distressing fact that maternal mortality had not declined was a matter of grave concern and a blot on the good health record of the country. Maternal mortality was a complex problem and did not admit of any simple solution. An investigation was being carried out by medical officers of the Ministry of Health, who were studying conditions in a number of areas where, in the last ten years, the mean of the maternal mortality-rate had been above the average for the country as a whole. About half of these areas had already been visited, and when the inquiry was complete the findings were to be examined by the medical department of the ministry in consultation with Sir Comyns Berkeley, and it was hoped that much might be learned from this piece of research.

---

[1] Organised on behalf of the National Council for Maternity and Child Welfare and a number of constituent bodies by the National Association for the Prevention of Infant Mortality.

Mr. Somerville Hastings emphasised the importance of the age-period of two to five years. A number of diseases and affections which might last throughout life had their origin in that period. Dental decay, tuberculosis, rheumatism, deafness, and nasal disease were among such complaints, and any disease at that age was liable to leave a scar on the constitution.

Dr. G. F. McCleary reported on the results of an investigation promoted by the National Society for the Prevention of Infant Mortality. An inquiry form had been issued to 514 local authorities in Great Britain and Northern Ireland, who were asked to indicate what measures were employed in their areas to promote the physical and mental welfare of children from two to five years of age. Replies were received from 369 authorities, and the measures most generally adopted were found to be supervision of toddlers in centres and by health visiting, provision of food (chiefly milk), treatment of minor ailments, and orthopædic and dental clinics. Little provision had been made for child guidance clinics, day nurseries, playrooms, and playgrounds, and—particularly deplorable—only 62 nursery schools, with accommodation for about 5000 children, had been established and officially recognised, in the whole of England and Wales. The chief obstacle in promoting the welfare of children between two and five was said to be parental ignorance and apathy in 96 out of 159 replies. Other causes were stated to be bad housing, poverty and unemployment, and financial stringency. Dr. McCleary said a study of the replies left him with the impression that the most urgent needs were more nursery schools and an extensive development of instruction in parentcraft.

Dr. Ethel Cassie (Medical Officer for Maternity and Child Welfare, Birmingham) said she was not convinced that a really good beginning had been made. The proportion of toddlers attending centres, even when special sessions were arranged for them, was disappointingly small, and some local authorities were content if these children received one visit a year from a health visitor, while the majority were not seen more than twice a year. She thought systematic medical inspection and home visiting the first necessities.

Dr. G. F. Still (National Institute for the Prevention of Infant Mortality) presided over the afternoon session, when the subject for discussion was Facilities for Convalescent Treatment of the Child under Five Years.

Dr. Margaret Hogarth (Divisional Medical Officer, L.C.C.) said that the London County Council arranged holidays for about 6000 children a year, but many of these were not strictly convalescent, and the accommodation for children under five was very small. The toddler was nobody's child, falling between the Ministry of Health and the Board of Education. This was very unfortunate in view of the great importance of the early years; the younger the child the more lasting were the results of illness or privation. Convalescence was carefully organised to ensure that children who had been really ill were sent to homes where skilled care was available. The home conditions to which children returned were most important; homes were visited and advice was given. In connexion with new housing schemes it would be a good thing if mothers could be helped with their budgeting and cooking. Provision of convalescence for young children was an urgent need and one which should be recognised by every local authority.

Dr. Leslie Housden spoke on the main causes of ill-health in the children of poor homes. These he considered to be emotional unrest and unhappiness (often due to over-large families), parental ignorance, poor feeding, lack of routine and discipline, and absence of fresh air and sunshine. He recommended simple education in non-technical language, inculcating a spirit of assurance and a belief that the new-born baby is generally healthy and only requires a mother's care to keep it so. The right course, he thought, was to concentrate on the teaching of mothercraft before marriage and to interfere as little as possible afterwards.

Dr. Alan Moncrieff urged the recognition of convalescent homes as an essential part of the national health services. Some conditions in young children demanded convalescence if they were to be completely cured. Chronic lung disease would largely disappear if children suffering from measles or whooping-cough could have a long period of convalescence. The same applied to tonsillectomy and chronic digestive disorders, and it was important that convalescent homes should take children earlier after acute illnesses. The length of stay must be adequate, three weeks being regarded as an absolute minimum.

(To be concluded)

MEDICINE AND THE LAW

Inquest on Human Arm Prohibited

In our issue of June 15th our correspondent from Australia described the unusual medico-legal problem associated with the discovery of a human arm in the body of a shark on the Coogie beach. The story is carried further in the *Times* of June 25th, where a message from Sydney describes the intervention of the Supreme Court of New South Wales to stop the inquest on the ground that a human arm does not constitute a body. It is understood that a man named James Smith has been missing in circumstances suggesting the possible theory that he was murdered and that his body was disposed of by throwing it to the sharks. The arm has been identified by tattoo marks and fingerprints as the arm of James Smith. Medical evidence indicated that it was apparently severed from a dead body. A man has been charged with the murder of Smith. At the instance of the accused the Supreme Court was asked to grant an order prohibiting the inquest from proceeding. Mr. Justice Halse Rogers granted a prohibition. His decision, he said, was based solely on the question of what constitutes a body; a coroner is obliged to view a body to assist him in reaching a verdict, and an arm is not a body; if the inquest proceeded, separate limbs, found in the jurisdictions of different coronerships, might be the subject of separate inquests.

No such point arose lately in England at the inconclusive inquest on the severed legs found on the Southern Railway; but then there was no accused person who had any occasion to object. In the Australian case the defence is entitled to rely on the difficulty and danger of proving a charge of murder where there is no body, and in that connexion may be interested to prevent an arm being treated as a body even in the coroner's court. The absence of a body did not prevent a conviction for murder in England not long ago in the case of the boy whose body, by the confession of the accused, had been disposed of by placing it on a burning dump. As regards inquests in England, Section 18 of the Coroners (Amendment) Act of 1926 enables the Home Office to direct an inquisition where a coroner reports a suspicious case in which, "owing to the destruction of the body by fire or otherwise, or to the fact that the body is lying in a place from which it cannot be recovered, an inquest cannot be held except by virtue of the provisions of this section." This section was intended to cover such instances as those of a body falling into a furnace or into a disused pit shaft; it was not meant to cover cases of mere mysterious disappearance without proof of death and with no evidence of destruction or inaccessibility. In the Sydney case there seems to be good prima facie evidence of the death of James Smith. There is no statutory definition of what constitutes a body for the purpose of inquests in England. The coroner is allowed considerable discretion. Many coroners of experience open inquests on almost any recognisable portion of a human being found in suspicious circumstances and, after taking the available evidence, adjourn for a reasonable period to allow for further search and inquiry. Under Section 6 of the Act of 1887, as explained by Section 19 of the Act of 1926, the High Court in England can quash an inquest and order a fresh inquest to be held where the discovery of new facts or further evidence makes this course desirable. In Coke's Reports (5 Rep. 110) and in Hawkins' Pleas of the Crown there are dicta which suggest that a small part of the body should not count as a body for the purpose of an inquest. It is usual nowadays, however, to assume that the advance in forensic medicine and the greater value of modern post-mortem examinations have contributed so much assistance in arriving at a verdict that the dicta of Coke and Hawkins are no longer so highly respected.

The Risks of Petrol and Explosives

The annual report of His Majesty's Inspectors of Explosives for the year 1934 (Cmd. 4934, price 9*d*.) shows the wide range of dangerous accidents due to ignorance or carelessness. The inspectors have authority under the Petroleum (Consolidation) Act as well as under the Explosives Acts and, as in previous years, they ask for greater publicity in the matter of the risks of using petrol in the home. They emphasise that petrol vapour, being much heavier than air, may flow out of a basin on to the floor, be carried by the draught to the nearest fire, and on ignition may flash back and envelop the person who is using it for dry-cleaning. They explain that the rubbing of fabrics (especially silks) in petrol may cause a spark of static electricity; such accidents lead to the upsetting of the basin with probably fatal results from the ensuing fire. Waste petrol poured down a drain has caused fire or explosion and has killed workmen in sewers. Several accidents occurred in 1934 during the fuelling of motor vehicles, either through leaving the engine running or through petrol falling on hot exhaust pipes or through acetylene lamps not being extinguished. One man was killed when the backfire from a stationary engine ignited spilt petrol. Persons were injured by explosion following a match struck to examine the contents of a petrol tank. The directions printed for use with Primus stoves state that no fuel other than paraffin or kerosene should be used; somebody at Morecambe used petrol with a fatal result. Special precautions are prescribed by law in the manufacture and conveyance of explosives and in their use in mines and elsewhere. Those concerned usually know the dangers. Children, however, run risks against which, as the report shows, it is hard to protect them. Thus two boys find a couple of grenades in an ashpit and throw them on a fire. A boy uses as a football something he sees in the road; it turns out to be a phosphorus grenade which has fallen off a dust-cart; it explodes when he kicks it. Boys find a shell on War Office land and throw it about till it goes off and injures them. A woman actually uses a 37 mm. shell to break up coal until the hammering at length explodes it. Evidently abandoned war relics and trophies are a constant peril. The chemical experiments of youthful students also lead to injury. A boy scrapes out the bore of a toy cannon previously charged with a mixture of potassium chlorate, amorphous phosphorus, sulphur, and aluminium dust; another boy mixes potassium chlorate and amorphous phosphorus and pours it into a drinking straw. In both cases there is an explosion. Articles in boys' papers are believed to stimulate these adventures; in 1927 there was an outbreak of accidents of this kind after the publication of an account showing how to produce coloured fires. His Majesty's inspectors of explosives say that the schoolboy's experiments are a breach of the law and that two Orders in Council of 1894 and 1905 prohibit the manufacture of fireworks containing compositions of sulphur or phosphorus in admixture with chlorates. Unfortunately a schoolboy's education probably does not yet extend to a knowledge of the multifarious Orders in Council under the Explosives Acts. Even if he knew that his experiment was a criminal offence, he might pursue it with no less ardour. The inspectors' report admits that it is a formidable matter to extract various statutory requirements from a mass of Acts, Orders in Council, and Orders of the Secretary of State. There certainly seems a strong case for simplifying the law as well as for reiterating for public information the dangers to which the report draws attention.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

NEUROSES IN MEDICAL PRACTICE

Dr. T. A. Ross, who delivered the Morison lectures before the Royal College of Physicians of Edinburgh last week, took as his subject the teaching of the neuroses to medical students. He began by emphasising the failure of the profession either to recognise or to treat the neuroses. Over a third of the patients seen in general practice, he said, are suffering from symptoms which are psychogenetic. The nature of the symptoms is seldom recognised; the patient's ill-health is perpetuated by imaginary diagnosis such as "nervous exhaustion" and he is advised to take things easily. The failure of the medical profession to recognise neurotic symptoms was, he said, responsible for the success of quack treatment. Quack treatment always promises cure, and this promise is sufficient to remove a large number of symptoms. Dr. Ross went on to consider the qualifications of the psychiatrist, the psycho-analyst, and the neurologist to teach the neuroses to medical students. He concluded that none of these specialists were suitable, but that the common forms of neuroses should be demonstrated to the student by the general physician who should be qualified to recognise and to treat them. He emphasised that the subject should be taught by the general physician and surgeon, so that the student should come to realise that in every case it is necessary to consider and adjust the patient's attitude to his symptoms, and to correct the fear which underlies nearly all neurotic symptoms.

Dr. Ross's lectures were much appreciated by the large numbers who attended. Dr. Ross said that his criticisms were not directed so much at the Edinburgh school as at others: he believed that the profession in Edinburgh were more alive to the importance of teaching the neuroses than were the teachers in other schools.

PARIS

(FROM OUR OWN CORRESPONDENT)

FOREIGN DOCTORS IN FRANCE

On June 27th the Senate passed the new provisions relating to the Practice of Medicine and Dentistry by Foreigners.[1] These do not affect existing practitioners but will make it more difficult in the future for foreign doctors or foreign nationals to earn their living in France. The movement, as will be seen below, is not a new one; it is generally held to be aimed at Rumanian nationals, of whom very many take their medical course in France. The provisions are set out now for the information of our readers, though the measure may be shelved at any rate until the autumn session.

In 1933 the French Government adopted a law which compelled every doctor who wished to practise in France to fulfil two conditions: he must, in addition to a university diploma, obtain the existing State diploma, and he must also become naturalised, unless he intended to proceed forthwith to one of the protectorates. Students were not required to naturalise. The French nation has found this an unsatisfactory arrangement, as more and more students have poured into French medical schools since it was passed. As a result both Chambers have received proposals for amending the situation. M. Armbruster, by whose name the law of 1933 is commonly known, had a motion on the Order Paper of the Senate some time ago, but its discussion was postponed by the death of the Minister of Education. In the meantime the Chamber of Deputies considered proposals brought forward by M. Cousin. The two propositions were so much alike that M. Armbruster's was, by consent, set aside in favour of a discussion in the Senate of M. Cousin's proposals as passed by the Lower House, with some minor modifications. M. le Gorgeu, the rapporteur, stressed the urgent need for action, pointing out that from 1925 to 1933, inclusive, the Prefecture of Police of the Seine had registered 1974 French and 402 foreign doctors, and that two-thirds of the 1530 foreign students attending French medical schools during 1934–35 probably intended to practise in France. It was made clear in the course of the discussion that a distinction must be drawn between foreign students who came to study French medicine and dentistry, returning home to practise, and those who seek to secure the benefits of practising their profession in France. For the first class no welcome is too warm; the second must be strictly limited in order that the French national may be protected in his profession.

THE NEW PROVISIONS

Article 1 limits the practice of medicine and dentistry in France to two classes of people: those holding the French State diploma or specially exempt under various laws of 1892–1927; and French citizens or subjects or those proceeding to countries under a French protectorate. (The words "ou sous mandat français" were added by the Chamber of Deputies, caused a certain amount of argument in the Senate and were finally dropped by consent.) In addition, foreign countries or doctors of foreign nationality may in certain cases obtain a dispensation from naturalisation under conditions of reciprocity. Such dispensations are to be given by individual decree. Special exemption is also provided for doctors from the Saar who were naturalised before March 1st, 1935.

Article 2 provides that a foreigner who possesses a diploma from his own country must pass all the French State diploma examinations but may be excused up to three years of study. The same regulations apply to those holding a French university degree of doctor of medicine except that they may be excused up to four years. This article provoked, said M. le Gorgeu, almost endless discussion before it was drawn up in the form presented to the Senate. Some people had even suggested abolishing the university diploma altogether in order to solve the problem described as "transforming a university diploma into a State one." Some of the associations of doctors and medical students wanted those who had degrees from another country to be compelled to go through the whole French curriculum, but this was regarded as a little excessive, and it was finally agreed and passed by the Senate without discussion in its present form.

Article 3 practically re-enacts the law of 1933 which does not allow foreign students any relaxation from the State diploma syllabus or examination however long they have studied in a foreign country. Any foreign student wishing to join a French medical school with a view to obtaining a State diploma must show that he has studied physics, chemistry, and biology, and must also possess all the qualifications necessary to enable him to enroll himself as a medical student in his own country. Subject to a slight amendment dealing with the position of Syria, this also was passed.

Articles 4, 5, and 6, which caused no discussion in the Senate, apply corresponding provisions to dentists and dental students and arrange for the investigation of foreign diplomas and degrees. During the first six months after the passing of this law prefects are charged with the duty of verifying the titles and diplomas of all doctors and dentists practising in France. Certain fines are laid down for practitioners who fail to comply with the requirements of verification.

The seventh Article is important in that it deals with the periods of time that must elapse before foreigners may practise, after obtaining their State diplomas. The Act of 1933 made no distinction between those who had completed their military service and those who had not. The present measure allows those who have carried out their military obligation to start practice as soon as they have obtained the State diploma, and the same privilege is extended to anyone who has served in the Army as a volunteer since 1914. For those who have not served, owing to exemption by a military board, and for women, there is to be a period dating from the acquisition of the diploma equal to the time of service which he or she has not served. Normally this means two years, but might be less for a man who had done part of his service and then obtained exemption. During this period doctors and dentists may do locum tenens work in order to earn a living and to keep their studies fresh in their minds. Foreigners living in France are not compelled to do military service if they are over 30, if bachelors; the age is 28 if they are married and have one child, and 27 if they have two children. This exemption often encourages foreigners to postpone naturalisation until they are 30, so as to escape conscription. This practice is naturally not favoured, and such persons are penalised by a clause in this article which says that any doctor or dentist who is exempted from military service on the grounds of age must delay starting practice for double the period of military service. In any case naturalised foreigners must wait five years before they may occupy any public position, unless they have served as volunteers on active service since 1914. There was some discussion as to the meaning of "public position," and M. le Gorgeu said that the Commission had deliberately refrained from defining it, and that it would be defined by regulation afterwards. It was certainly not intended to include free medical service to the poor, or vaccination, or to interfere with the practice of his profession by a foreign specialist who happened to be the only one available in a country district.

---

[1] A copy of these new provisions is available in this office for inspection.—Ed. L.

The provisions are not to be retrospective; any foreign doctor who already holds a public office in France will continue to hold it.

An amendment introduced by M. Maurice Viollette sought to reinstate a clause which had been put in by the Chamber of Deputies and deleted by the commission which had prepared the agreed Bill for the Senate. This clause exempted from the above conditions foreign students who had actually started their studies and who applied for a naturalisation within three months. M. Viollette argued that it was very unfair to slam the door in the faces of students who had been told in 1933 that their position was safe. He provoked some applause for his point of view, but M. Armbruster and M. le Gorgeu declared that if a mistake had been made in 1933 it must be put right, and that French nationals must come before everyone else. The amendment was lost by 253 votes to 28. An amendment moved by M. E. Sari exempted foreign students who had married French women and become the fathers of French children and had already applied for naturalisation.

Article 8 repealed previous enactments contrary to the new one.

THE PARISIAN'S CHANGING MENU

The Parisian of to-day does not, it would seem, eat what his father ate 30 years ago. Various investigators have recently come to the conclusion that bread is rapidly going out of fashion and milk and butter are coming in. Opinions differ as to the reasons for the Parisian's flight from bread. Some blame the intrinsic qualities of the bread itself, which they find deplorable, and others maintain that it is deserted for milk, butter, and other good things because the standard of living has risen, and the facilities for conveying and storing perishable foodstuffs have been enormously improved; the milk in Paris a hundred years ago was highly diluted sewage with an unstinted supply of typhoid and paratyphoid bacilli. Thirty years ago, according to Dr. A. Gauducheau (Rev. d'Hyg. et de Méd. Prévent., June, 1935, p. 434), the daily menu of the average Parisian included 420 g. of bread, 213 g. of milk, and 28 g. of fat, including butter. In 1930, he ate only 320 g. of bread, or 24 per cent. less than he ate at the end of last century. But his consumption of milk has risen to 400 g., and his consumption of fats to 70 g. It may be that his calorie consumption has changed but little; what has changed is the source of his calories. It has been calculated that the peasant on the land gets half his calories from his bread which costs less than a quarter of his complete bill of fare. In well-to-do families, however, the cost of bread is hardly one-tenth of the food bill.

THE SECOND INTERNATIONAL CONGRESS OF MENTAL HYGIENE

That tireless and provident organiser, Mr. Clifford W. Beers, has already reached an advanced stage in his preparations for the Second International Congress of Mental Hygiene which is to be held in Paris, July 27th–31st, 1936. His preliminary programme contains many distinguished names and the titles of many papers on interesting subjects. Prof. Henri Claude will be the honorary president, and Dr. E. Toulouse, president of the congress and of its executive committee. Dr. A. Ley will be the vice-president of the executive committee, Dr. G. Genil-Perrin, secretary-general, and M. Robert Demachy, treasurer. The president of the programme committee will be Dr. René Charpentier, to whom all inquiries about the programme of the congress should be addressed at 119, Rue Perronet, Neuilly-sur-Seine (Seine), France. The address of the secretariat of the congress is 1, Rue Cabanis, Paris, XIV. Every "adherent member" will be asked to contribute 125 francs, and every National Mental Hygiene League 500 francs towards the expenses of the congress. Among the Anglo-Saxons listed to speak are Dr. C. S. Myers, F.R.S. (London), on mental hygiene and intellectural work; Prof. W. A. White (Washington) on the prevention of alcoholism; Prof. D. K. Henderson (Edinburgh) on the individual and social prevention of suicide; and Sir Hubert Bond (London) on a scheme for an international classification and nomenclature of mental disorders.

MATERNAL MORTALITY COMMITTEE

A CONFERENCE called by the Maternal Mortality Committee[1] was held on June 25th in the Livingstone Hall, the chair being taken by Lady Denman. The morning session was opened by Dame Janet Campbell, who explained the policy of the committee; the afternoon session by Dr. Topping, who dealt with the scheme which he had initiated at Rochdale by which the maternal mortality-rate there had been so appreciably reduced.

The speakers included Mrs. Baldwin, who urged the initiation of local committees to popularise antenatal clinics; Dr. Fairbairn, the president of the

---

[1] The committee is constituted as follows: Mrs. H. J. Tennant, Lady Iveagh, M.P., Miss G. Tuckwell, Lady Barrett, M.D., Mrs. Barton, Mrs. Bramwell Booth, Lady Margaret Boscawen, Lady Cynthia Colville, Lady Crozier, Lady Erleigh, Lady Fitzalan, Miss Alice Gregory, Miss Haldane, Mary Lady Harcourt, Lady Hillingdon, Mrs. Hislop, Mrs. Hubback, Mrs. Randall Hosking, Mr. Kershaw, Lady Noel-Buxton, Mrs. William Piercy, Miss Sutherland, and Mrs. Usher.

British College of Obstetricians and Gynæcologists, who commended the policy as a whole; Mr. Eardley Holland, also representing the British College, who emphasised the importance of a post-graduate training for doctors; Prof. James Young, of the Postgraduate Medical School; Dr. Harold Waller, of the Royal College of St. Katherine, who urged that the care of mother and baby should everywhere be the responsibility of one and the same public health authority, and who also emphasised the importance of a post-graduate training; and Miss Gregory, of the British Hospital for Mothers and Babies, who dealt with the training of midwives. Dr. Picton dealt with the Cheshire Antenatal Scheme and Lady Williams with the scheme in the Rhondda Valley.

The policy of the committee was summarised for the meeting as follows.

1. The institution in each area of a maternity service which, while paying attention to the varying needs and character of different localities, shall enable all women to obtain adequate antenatal, natal, and postnatal care. To this end special attention shall be paid to the following points :—

(*a*) Antenatal, natal, and postnatal care should be under the same medical guidance.

(*b*) Midwifery practice should be limited to doctors with post-graduate training and practice in obstetrics.

(*c*) Local schemes should be encouraged which would enable private practitioners so equipped to take part in the maternity services.

(*d*) The need of skilled obstetricians for all complicated cases.

(*e*) The extension of the period of midwives' training to two years.

(*f*) The advantage of a service of salaried midwives working under the direction of a hospital, a nursing association, or the local authority.

(*g*) The provision of a sufficiency of maternity beds, in properly equipped hospitals, for complicated cases, and for patients whose condition or home circumstances entail potential risk.

(*h*) An improved domiciliary service for women attended by a doctor or midwife; such service to provide trained maternity nursing.

(*i*) An adequate after-care service which is seldom, if at all, provided in maternity and child welfare schemes. Its object should be to ensure that the period of hospital and domiciliary care is sufficient for the mother's full restoration to health, and that the infant's early hold on life is secure. To this end the whole of the arrangements for the care of mother and baby should everywhere be the responsibility of one and the same public health authority.

2. Since we have not yet succeeded in applying effectively existing knowledge to the reduction either of maternal morbidity and mortality, or of the high death-rate of new-born infants, it is desirable that there should be established carefully planned model schemes in selected urban and rural districts. As part of the work thus undertaken, or as a separate task, an investigation is urgently needed of the extent to which childbirth is followed by disability. A special grant from public funds should be available for the encouragement of such schemes.

3. Compulsory immediate, confidential notification to the M.O.H. of the local supervising authority of all deaths occurring during pregnancy, and of all those following or associated with childbirth and abortion.

The following societies accepted the invitation to send delegates :—

Queen's Institute of District Nursing; Central Women's Advisory Committee of the National Union of Conservative and Unionist Associations; Women's Section of the Labour Party; Standing Joint Committee of Industrial Women's Organisations; Society of Medical Officers of Health; British Legion, Women's Section; College of Nursing; Catholic Women's League; National Women Citizens' Associations; Fabian Society, Women's Section; Midwives' Institute; National Council of Women; National Baby Week Council; National Council for Maternity and Child Welfare; National Council for Equal Citizenship; National Council of Evangelical Free Churches, Women's Council; Salvation Army; Women Public Health Officers' Association; Women's Coöperative Guild; National Liberal Federation; National Federation of Women's Institutes; Union of Jewish Women; British College of Obstetricians and Gynæcologists.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdrs. A. Craig to *President* for course; E. Heffernan to *London*; J. F. M. Campbell to *Victory* for R.N. Hospl., Haslar; A. W. North to *President* for service inside Admiralty; F. G. Hunt to *President* for R.A.F. Medical Officers' course; and O. D. Brownfield to *Ramillies* addl.; and A. W. Cocking to *Valiant*.

Surg. Lt.-Comdrs. R. G. Anthony to *Drake* for R.N. Hospl., Plymouth; and F. G. V. Scovell to *Pembroke* for Sheerness Dockyard.

Surg. Lt.-Comdrs. (D.) O. J. Barrable to *Pembroke* for R.N.B.; L. A. Loules to *Drake* for R.N.B.; and T. Hunt to *Victory* for R.N.B.

Surg. Lts. L. G. Yendoll to *Victory* for R.N. Hospl., Haslar; W. A. Ryan to *Ladybird*; W. Greaves to *Terror II* for Singapore Naval Base; and A. Long to *Pembroke* for R.N. Hospl., Chatham.

The following promotions have been made :—

Surg.-Comdr. to Surg.-Capt.: E. C. Holtom, O.B.E., E. Moxon-Browne, H. R. B. Hull, and C. M. R. Thatcher.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Comdrs. W. H. Butcher to *Caledon*, and R. Hall to *Cardiff*.

ROYAL ARMY MEDICAL CORPS

TERRITORIAL ARMY

Lt.-Col. & Bt. Col. E. A. C. Fazan, M.C., T.D., from 5th Bn. R. Sussex R. (supern.), to be Lt.-Col. & Bt. Col.

Capt. A. Angus to be Maj.

Lieuts. to be Capts.: A. W. Henderson, W. G. Bisset, H. Sissons, T. N. Rudd, W. P. Purvis, J. T. Watkins, and R. D. W. Butler.

D. H. Young (late Cadet C.S.M., Queen's Univ. Contgt., Canadian O.T.C.), to be Lt.

Supernumerary for service with the O.T.C.—Lt. W. M. Nichols to be Capt.

ROYAL AIR FORCE

The increased work caused by the expansion scheme has led to a division of the duties of the Central Medical Board. No. 1 Central Medical Board at 3-4, Clement's Inn, London, W.C., will carry out all medical examinations in connexion with the Central Medical Establishment with the exception of those for *ab initio* entries. No. 2 Central Medical Board at Astor House, Aldwych, W.C., will carry out all *ab initio* medical examinations. The personnel of both medical boards will be held on the establishment of the C.M.E.

The undermentioned promotions have been made :—

Group Capt. to be Air Commodore: W. Tyrrell, D.S.O., M.C.

Wing Comdrs. to be Group Capts.: D'Arcy Power, M.C., K. Biggs, M.C., and E. W. Craig, M.C.

Squadron Leaders to be Wing Comdrs.: V. R. Smith, P. C. Livingston, C. P. Barber, A. Briscoe, C. T. O'Neill, O.B.E., J. K. R. Landells, and E. D. D. Dickson.

Dental Branch.—Squadron Leader L. Somerville-Woodiwis, L.D.S. is promoted to the rank of Wing Commander.

Flight Lts. W. D. Guyler to Home Aircraft Depôt, Henlow; J. E. Willoughby to Headquarters, Coastal Area, Lee-on-the-Solent.

CORRESPONDENCE

TREATMENT OF SCABIES

To the Editor of THE LANCET

SIR,—Dr. R. M. Fraser in your issue of May 25th rightly refers to the prevalence of scabies as a subject of general public interest, but some of the points which he raises provide matter for discussion. The answer to his query regarding the use of sulphur in the treatment of scabies seems to lie in the desire for a slowly volatile substance, which will penetrate the burrows made by the mites while causing the minimum amount of damage to the tissues of the host. Norman Walker in his "Introduction to Dermatology" (8th edition) says: "Were we as familiar with the causes of all infective inflammations, and had we as sure a remedy for their destruction as we have for the acarus in sulphur, the treatment of the diseases of the skin would be very much simplified." Undoubtedly treatment by sulphur, involving as it does in a proportion of cases an irritant dermatitis, is far from ideal, but it may be presumed that dermatologists throughout the world would not be content to employ such treatment without having sought, apparently unsuccessfully, an alternative which destroys the invader without damaging the host.

The substances mentioned by Dr. Fraser are not familiar to me, but it appears that their use may be open to objection. One would hesitate to expose the whole body, as is necessary in treating a case of scabies, to the action of a substance sufficiently powerful to destroy beetles. There also must be some doubt as to the efficacy of a highly volatile substance, the active principle of which would be just as likely to be volatilised into the atmosphere as to penetrate burrows beneath the skin. The difficulty of attaining complete sterility of the skin before surgical operations throws a sidelight on the problem of penetration beneath the surface of the skin.

The treatment of scabies in the Army, though differing to no great extent from that employed in civil practice, probably attains better results for the reason that the patients are controlled in hospital. In the "Danish method," which is generally employed, the patients are made to bath and scrub themselves thoroughly on admission. Marcussen's ointment is then applied and the patient is put to bed, a second application of ointment being made 12 hours later. The patient remains in an atmosphere of sulphur for 24 hours. These two applications of sulphur ointment are usually sufficient to kill the parasites. At the end of 24 hours the patient is again bathed and provided with a complete change of clothing and bedding. Meantime all his clothing and bedding has been disinfected.

Application of an ointment may be a messy method of treatment, but it at least ensures prolonged contact of the drug with the surface to which it is applied.

It will be agreed that the ambulatory treatment necessarily employed in most cases in civil practice is beset with considerably more difficulty and is probably less satisfactory, but the results obtained in the Army are reasonably good and the treatment is relatively inexpensive.

I am, Sir, yours faithfully,

R. G. SHAW.

June 22nd.

Lieut.-Colonel, R.A.M.C.; Specialist in Dermatology, Aldershot Command.

AGGLUTINATION OF VIRUS BODIES

To the Editor of THE LANCET

SIR,—In your last issue Dr. M. H. Gordon raises the question of priority in connexion with the demonstration of the specific agglutination of elementary bodies by immune sera and criticises a statement in a recent paper by Schlesinger, Signy, and Amies (THE LANCET, May 18th, 1935, p. 1145) that this phenomenon was first described by Ledingham (1931) in the case of vaccinia and fowl-pox. May I as the person concerned in, but not responsible for, the statement in question, be allowed the privilege of commenting upon it? Dr. Gordon's historical researches do not seem to have been either very profound or very critical as he has contented himself with statements copied from one review to another but all pointing to an earlier demonstration of this reaction in 1913 by Paschen and Jakobsthal. The facts are these, and they were familiar to me before I undertook the task of securing pure suspensions of the elementary bodies of vaccinia and fowl-pox, for serological tests, and of which the paper by me in 1931 (THE LANCET, 1931, ii., 525) represented the outcome. That paper contains the following paragraph: "The only evidence I can find bearing on the influence of specific immune serum on these elementary bodies is that recorded by Prof. Paschen, who found and figured in stained preparations of precipitates obtained by the interaction of immune serum and lymph from vaccinated children, agglutinated masses of elementary bodies."

This is the substance of a statement by Paschen (Deutsch. med. Woch., 1913, xxxix., 2135) who, in the course of a lecture on vaccinia and variola referred to some work he had carried out with his colleague E. Jakobsthal. What he and his collaborator actually demonstrated was a precipitation reaction taking place between lymph from vaccinated child and rabbit immune serum, in the course of which the elementary bodies present in the lymph were found to be clumped on application of staining methods. "In dem Präzipitat konnte ich nun neben amorphem Eiweiss die Körperchen in grossen Haufen agglutiniert nachweisen."

That Paschen and Jakobsthal's experiment represented the nearest approach that could be made at that time to the demonstration of agglutinins in immune sera for elementary bodies was admitted by subsequent critical reviewers (see e.g. Winkler Erg. d. allg. Path. u. Path. Anat., 1924, xxi, 45), but, so long as precipitation and agglutination effects ran concurrently owing to impurity of the virus suspension the demonstration of specific agglutination of elementary bodies by the corresponding immune sera had to wait for new methods and for nearly twenty years. All honour, however, to Prof. Paschen for making such an intriguing observation at this early date, and may I add here my tribute of respect and thanks to a veteran worker and friend who gave me much assistance when I took up the study of these bodies by new methods and has since maintained a lively interest in them. The full significance of Paschen's observation was realised only when it was shown that elementary bodies in pure suspension were clumped by immune sera and when later my colleague Dr. Eagles and I were able to supply experimental proof of the ætiological connexion between the virus of vaccinia and the bodies of Paschen. The sentence, therefore, which Dr. Gordon criticises does not seem to require any substantial qualification in the interests of historical accuracy. One thing leads to another, and in these days it is always dangerous to say who did or did not first "describe" or "discover" anything, unless the thing described or discovered is precisely formulated.

May I be permitted to add, with reference to Dr. Gordon's further expressions of opinion in the course of his letter, that the microscopic agglutination test for variola elaborated by my colleague Dr. Amies would seem to me more scientifically founded from an immunological point of view than the macroscopic flocculation test with virus extracts, in that the former represents a simple and uncomplicated reaction between the elementary bodies of variola and the serum of the small-pox patient. In my opinion no pains should be spared to render the reagents employed in serological work with viruses the simplest and purest possible. The effective study of elementary bodies requires a lengthy apprenticeship and is in my view indispensable for any real advance in our knowledge of the biological nature of viruses.

I am, Sir, yours faithfully,
J. C. G. LEDINGHAM.
Lister Institute, London, June 29th.

ACHLORHYDRIA IN PYLORIC CARCINOMA

AN EARLY REFERENCE

To the Editor of THE LANCET

SIR,—Dr. J. Douglas Robertson has given us, in your last issue, some valuable observations on the development of achlorhydria in obstructive carcinoma of the pylorus. His conclusion that this is caused by the attendant gastritis must almost certainly be correct.

As a matter of historical interest and evidence of the early attention devoted to the pathological chemistry of the stomach by a physician of the Guy's school, I would refer him to papers by Golding Bird, in the *London Medical Gazette*, 1841–42, pp. 391 and 426. With the very laborious methods of quantitative analysis then available Golding Bird clearly demonstrated a steady decline in the percentage of hydrochloric acid in obstructive pyloric carcinoma, and also the simultaneous rise in the organic acids. He assumes, however, that the disappearance of the natural acid was due to failing vital powers.

I am, Sir, yours faithfully,
Wimpole-street, W., June 29th. JOHN A. RYLE.

FRACTURES OF THE CALCANEUS

To the Editor of THE LANCET

SIR,—May I congratulate Mr. D. C. Corry on his paper on fractures of the calcaneus involving the subastragaloid, appearing in your issue of June 22nd. I agree with him that it is essential to obtain movements of the subastragaloid and mid-tarsal joints in order to ensure a foot free from pain. The following case is of interest:—

In November, 1933, a postman reported at hospital with a history of a fall off a ladder 15 feet high on to his left heel 11 weeks previously. He had been in bed for ten days following the injury and had tried to return to work 8 weeks after the accident, but had found the foot so painful that this was impossible. On examination, movements at the ankle-joint, subastragaloid, and mid-tarsal joints were all markedly limited and painful on forcing them. There was also much periarticular thickening involving the ankle and tarsal joints. The foot was held in a pronounced valgus position. The X ray films showed a fracture of the calcaneus extending into the subastragaloid joint with shortening and widening of the bone. Impaction had taken place between the fragments and there was a good deal of overlapping. At first sight the above case presented as grave an outlook as possible, and a subastragaloid arthrodesis was considered. With two manipulations under an anæsthetic and regular treatment consisting of faradic contractions and movements, the patient was able to carry out his work as a postman at the end of 3½ months with the aid of a valgus insole. After 15 months of work he reports that the foot is still free from pain and the movements good, but it occasionally aches at the change of weather.

Pain in these cases is often described as being due to an arthritis in the subastragaloid joint. But if movement is obtained in this joint with freeing of the soft structures over the tarsal joints, a perfectly useful foot can often be obtained. Subastragaloid arthrodesis requires a patient to lie up for 4–8 months, and even after that period the foot may be painful unless the soft structures around the tarsal joints are treated. I am, Sir, yours faithfully,

Wimpole-street, W., June 29th. W. ELDON TUCKER.

LIGATURE OF SPLENIC ARTERY FOR ADVANCED SPLENIC ANÆMIA

To the Editor of THE LANCET

SIR,—I have read with great interest in your issue of April 20th the article on this subject by Mr. R. Burns-Watson. The operation of ligature of the splenic artery was referred to by J. W. McNee in his Lettsomian Lectures of 1931 (Brit. Med. Jour., 1931, i., 413) as likely to be of value in several types of splenic enlargement. I had an opportunity of discussing this question with Dr. McNee during the centenary meeting of the B.M.A. in London, and at that meeting I read a paper on Splenectomy with special reference to Splenomegalies in the Tropics. In this paper, published in the *Indian Medical Gazette*, of January, 1933, I stated that ligature of the splenic artery had been successfully performed on previous occasions and urged that this manœuvre was worthy of more extensive trial, particularly in India, where splenomegalies of the splenic anæmia type are by no means uncommon. Splenectomy is a very severe operation for such cases when extensive adhesions are present.

I have had no opportunity for performing this operation myself, as my present duties are mainly administrative, but I had hoped that other surgeons in India would be tempted to try this alternative and simpler procedure. Ligature of the splenic artery is not always easy, as it may be difficult to separate the artery from the greatly engorged veins, and ligature of the whole pedicle though easier would probably be more risky. Complications are also to be considered, and among these portal thrombosis is a serious possibility. It is gratifying to note that a surgeon in New Zealand has provided another example of the successful result of splenic ligature, and this time for an advanced case of so-called splenic anæmia.

In the *Indian Medical Gazette* of May, 1935, an article appears on Splenectomy for Tropical Splenomegally by A. N. Palit. Ten cases were operated on with a successful result in nine. But the more severe cases were apparently avoided, as ascites, signs suggesting cirrhosis, fixed immobile spleen, and so forth, are mentioned as contra-indications. It is just in these types of enlarged spleen that splenic ligature may be of value, while such cases if left to themselves usually terminate fatally. Will some surgeon in India provide us with more evidence as to the value of splenic ligature in these cases of the splenic anæmia type, which can only be removed by splenectomy with a high mortality risk. Reference is made in the article in the *Indian Medical Gazette* to ligature of the splenic artery, but only to dismiss it as a risky and not always an easy procedure.

Has splenic ligature ever been practised for splenic leukæmia, and with what result?

I am, Sir, yours faithfully,
F. P. CONNOR.
Madras, India, June 10th.

POTASSIUM CHLORIDE IN MYASTHENIA GRAVIS

To the Editor of THE LANCET

SIR,—The observations of Laurent and Walther on the influence of potassium chloride on myasthenia gravis are of very great interest. I have been able to confirm their results in two severe cases of the disease. Potassium chloride (12 grammes) in a tumblerful of water was given to each patient at 3.30 P.M. when the effect of an injection of Prostigmin 5 c.cm. had worn off. A decided improvement in the symptoms occurred, which lasted for about two hours. One patient had slight nausea and a feeling of heat.

A case of familial periodic paralysis, whose attacks occur during sleep and can be brought on at will by eating sugar late in the evening, was found by Dr. E. N. Allott to have abnormally low serum potassium during the attacks. The blood was taken about two hours before the paralysis wore off. During the intervals the blood potassium was normal.

	During the intervals.	*During an attack.*
Serum potassium ..	17·8 mg.%	10·0 mg.%
,, ,, ..	19·3 mg.%	12·6 mg.%

The serum calcium during an attack was 9·7 mg. per cent. and 10·3 mg. per cent. during an interval.

I have to thank Dr. W. D. Wiggins, the medical superintendent of the hospital, for permission to publish these observations.

I am, Sir, yours faithfully,
M. B. WALKER.
St. Alfege's Hospital, S.E., June 24th.

NON-TOXIC ANTIMONY ADMINISTRATION

To the Editor of THE LANCET

SIR,—Judging from the analogy of allied parasitic worms, trivalent antimony derivatives should prove more serviceable in the treatment of filariasis than pentavalent compounds, and it would likewise appear that those which contain the greatest quantity of antimony metal in a non-toxic form should prove most effective in destroying the embryos in the blood stream and lymphatic system. In human trypanosomiasis L. Van Hoof[1] has shown that a total of 0·98 g. of antimony metal is well tolerated by any patient when administered in one of the new organic antimony preparations which are on trial. This is in excess of that contained in the maximum total dose of tartar emetic and suggests that these allied preparations, which seem superior in action to tartar emetic in the treatment of both trypanosomiasis and schistosomiasis, are well deserving of trial in the destruction of microfilariæ.

For the last 20 years I have investigated the least toxic methods of treating bilharzia disease and similar parasitic conditions, but impaired hearing has prevented me obtaining any recent official post or other facilities for continuing this study on an adequate scale in Natal. I should be grateful to hear from anyone who could enable me to investigate further the uses of non-toxic antimony derivatives or would care to correspond with me on the subject. There would be little cost in obtaining the medicines, for a thorough scientific investigation of their relative values and what has already been completed indicates that antimony may now be administered without risk to the numerous skin conditions for which it has always been recommended.

I am, Sir, yours faithfully,
F. G. CAWSTON, M.D.
Britannia Buildings, West-street, Durban, June 9th.

CLEFT PALATE

To the Editor of THE LANCET

SIR,—I feel that I cannot allow Mr. David Levi's letter on this subject in your last issue to pass without comment. The whole object of the procedures advocated by myself has been that of restoration of function, and this can only be attained by operation based on sound anatomical and physiological principles. The proof of success lies not in the appearance of the suture line or in the apparent mobility of the palate, but in the ability of the patient to open and close the nasopharyngeal valve. There are many simple tests of proficiency in this matter, such as snorting and the ability to inflate balloons, &c. Restoration of this function is all that surgery can do and is, therefore, the aim of any repair of the palate; there is no need to do more than this and to do it in the neatest and most workmanlike fashion.

It is interesting to observe Mr. Levi repeating the remark, that the palatopharyngeus plays such an important part in speech. In my dissections of many normal palates and one or two cases of cleft palate I have been quite unable to correlate the action of this muscle with the speech mechanism as observed in life in the normal person. Again it is difficult to understand Mr. Levi's horror at destruction of the tensor palati, since, as my colleague Mr. James Whillis and myself have been able to show, the principal function of the tensor is not concerned with speech.

Mr. Levi says:

> "Pharyngoplasty, which was attempted even in pre-Listerian days, has been alternately used and discarded by surgeons the world over. It was brought into prominence by Rutenberg in 1876; he made a transverse incision in the pharynx and sutured it longitudinally. Botey in 1908 excised an ellipse from the posterior pharyngeal wall, and sutured the edges, while Sir Robert Woods in 1927 electrocoagulated the posterior pharyngeal wall. Mr. Wardill has modified and reintroduced Rutenberg's operation—evidently with some success—but I cannot help thinking that narrowing of the lumen of the nasopharynx is liable to interfere with the function of the palatopharyngeal sphincter."

It is news to me that, since pre-Listerian times, pharyngoplasty has been alternately used and discarded by surgeons the world over. Information at present in my possession would suggest that pharyngoplasty is gaining an increasing number of adherents. To say that I modified and reintroduced Rutenberg's operation is entirely incorrect, since my knowledge of Rutenberg, like most other peoples, dates from the publication of Dorrance's book. Pharyngoplasty, as designed by myself, was based entirely upon original anatomical research, and was not in any way founded on Rutenberg or on any one else. Since Dorrance produced his book, I have looked up Rutenberg's papers, and as I read them, admittedly with an imperfect knowledge of German, it would appear that he aimed at producing a pharyngeal scar, and only as an afterthought offered the suggestion of suturing in a longitudinal direction.

---

[1] Ann. Belgian Soc. Trop. Med., No. 4, 1933, vol. xiii.

It is obvious that the method described by him was bound to be a failure and could not in any way approach the results of pharyngoplasty as carried out at the present time. Undoubtedly Rutenberg's ideas were sound, and it must be common knowledge that cases of cleft palate, subjected to removal of adenoids, very often speak very much worse after the operation. This is surely evidence in support of a need for something in the pharynx against which the palatal mechanism can act.

Mr. Levi is opposed to pharyngoplasty on the grounds that he, "cannot help thinking that narrowing of the lumen of the nasopharynx is liable to interfere with the function of the palatopharyngeal sphincter." The proof of the pudding is in the eating, and in the previous publication of my results I think I have amply demonstrated that pharyngoplasty restores the nasopharyngeal sphincter mechanism. Fortunately, Mr. Levi presents alternative methods of treatment which, he says, offer the greatest chance of success, and I think it is only fair to British surgery, and to sufferers from cleft palate in general, that he should give this benefit to others, laying his cards on the table and publishing his methods in detail together with a complete record of his results.

Finally, may I repeat, the aim of surgery of cleft palate is to restore the sufferers to normal with as little scarring, surgical or psychological, as possible. This can only be done by sound operation followed by a normal existence in which attention is not specially directed towards the child's deformity, such as inevitably occurs with speech training. I repeat, the necessity for speech training is either evidence of surgical failure or having missed the surgical boat.

I am, Sir, yours faithfully,

Newcastle-upon-Tyne, July 1st. W. E. M. WARDILL.

RADIOGRAPHY UPSIDE DOWN

To the Editor of THE LANCET

SIR,—I was interested in the annotation under this title in your issue of May 25th. Gravity certainly has a definite effect on the thoracic viscera and in the case of pneumothorax the intrapleural pressure will be found to vary considerably with the position of the patient. I have known a pressure of −12 −2 with the patient lying on the healthy side and the pneumothorax cavity uppermost to be converted into one of −5 +1 when he turned round. Presumably this change is caused by the weight of the viscera, and it is therefore important to have the patient in the same position at each refill if pressures are to be compared.

When the base of the lung is obscured in a case of effusion it can be seen by placing the patient on his side or even standing him on his head. This also enables one to get a view of the diaphragm and to detect early adherence of the base to the chest wall, a very common occurrence in effusion complicating pneumothorax. I published a short article on this subject with diagrams from X rays some years ago (Brit. Med. Jour., 1927, i., 135).

I am, Sir, yours faithfully,

L. S. T. BURRELL.

New Cavendish-street, W., July 1st.

PANEL AND CONTRACT PRACTICE

Physical or Mental Disability in an Insurance Practitioner

Clause 4 (4) of the Terms of Service provides that when the insurance committee, after consultation with the panel committee, are satisfied that owing to the continued absence or bodily or mental disability of an insurance practitioner, his obligations under the terms of service are not being adequately carried out, they may, with the consent of the Minister, give notice to the insured persons on his list that the practitioner is no longer in a position to carry out his obligations under the Terms of Service. This means in effect that although the practitioner's name is not automatically removed from the Medical List his insurance practice is scattered. The clause is not frequently brought into operation, but the London committee has just consulted with the local medical and panel committee who have concurred with their opinion that owing to the advanced age and enfeeblement of a practitioner he is not in a position adequately to discharge his obligations.

The practitioner, who registered in 1874, joined the Medical List in 1929 and changed his surname to that of his deceased predecessor with a view to carrying on the practice for the benefit of the children of the predecessor until one of them should become qualified, and so could succeed to the practice. Having regard to the special circumstances the committee consented to his employing an assistant, who, however, did practically the whole of the work, and early in 1932 the committee decided to withdraw their consent to the employment of an assistant. The practitioner appealed to the Minister and the appeal was upheld largely, it appears, on the understanding that the arrangement was likely to terminate at an early date as a result of the anticipated qualification of one or other of the children. The son qualified early in 1934 and the committee, with the concurrence of the panel committee, decided in January, 1935, to withdraw consent to the employment of an assistant as from March 31st, 1935. The son then joined the Medical List but did not succeed to the practice, and the practitioner indicated that he was introducing the son to the practice for a period of six months. The committee took the view that it had long been established that the practitioner's personal services in connexion with the practice had been very limited and they felt that the circumstances attending the so-called introduction were likely to differ in no essential particular from those which had prevailed during the past six years, and that these unsatisfactory arrangements should now be terminated.

The committee are now in a position to make a representation to the Minister of Health that owing to the advanced age and enfeebled condition of the practitioner he is not in a position adequately to discharge his obligations under the Terms of Service, with a request for the Minister's consent to the committee's making other arrangements for the medical treatment of his patients.

The Whitsuntide Conferences

Each year, round about Whitsuntide, conferences of various friendly and other societies are held, and it is rare for the medical profession to escape more or less vehement criticism, particularly in relation to their duties under the National Health Insurance Act. This year the attack centres on the profession in general rather than on the insurance doctor as such. We were told, it is reported, by a medical speaker at a congress held at Bridlington, that the medical profession has deteriorated, that it has become thoroughly commercialised, that insured persons are not reckoned as human beings but as so many units per head for profit making by big concerns, that there is a lack of proper surgery accommodation, and that there is no careful selection of doctors for working-class districts. We are, however, glad to be assured that the bulk of the doctors would like to give the insured person a square deal. All this from a medical man is rather astonishing. If there is a lack of proper surgery accommodation, surely the insurance committee, if made aware of it, would take appropriate action, but it is neither to be expected nor desired that committees should take unto themselves a roving commission to test the conditions under which doctors are carrying on their work. The careful selection of doctors for working-class districts is another flight of fancy which hardly bears examination in the cold light of reason. Insurance doctors with the largest lists are almost invariably found in the working-class districts, and in these days of keen competition it is the man who does his job, and not the slacker, who succeeds. When it is remembered that in London alone during 1934 no less than 8,482,787 prescriptions were issued, each of them representing a consultation and a potential complaint, it is significant that in only 39 cases was it necessary for the medical service subcommittee to investigate questions concerning insurance doctors.

Whitewash

A member of an insurance committee who recently alleged that medical members of medical service subcommittees went "for the purpose of whitewashing their colleagues" was invited at the next meeting by a medical member either to resign from the committee or to withdraw his remark and apologise to the members of the subcommittee. The member withdrew the remark and apologised. This subcommittee acts in a quasi-judicial capacity, and it is the duty of its members to lean neither to the side of the "defence" nor to that of the "prosecution." It must be remembered, however, that on the purely medical aspect of cases doctors tend to share a point of view differing somewhat from that of the layman. This is the outcome not only of their common training but of their knowledge of the difficulties of coping with the emergencies of practice, and should not be attributed to a "trades union" sentiment.

OBITUARY

JAMES ROBERTSON RIDDELL, F.R.F.P.&S. Glasg.

MEDICAL ELECTRICIAN, WESTERN INFIRMARY, GLASGOW

THE death occurred on Saturday, June 29th, at Bearsden, Dumbarton, of Dr. James Riddell, a pioneer radiologist. He was born at Glasgow in 1873, the son of the Rev. John Riddell, of the Wynd church, and received his medical education at the Royal Infirmary, Glasgow. He qualified in 1897 with the Scottish double diploma and held the appointments of house physician and house surgeon at the Infirmary. He was from the beginning of his professional career interested in radiology; though he was for a time in general practice, he soon began to work under the late Dr. John M'Intyre, the well-known laryngologist, who was surgeon to the Royal Infirmary and in charge of the electro-therapeutical department. These were the early days of the introduction of X ray work into medicine and Riddell was immediately interested in the developments so promised. A radiological department was instituted in the Infirmary, much practical work was published as a result, while Riddell became the recognised X ray specialist in the city. On the outbreak of war he saw service in the East, was radiologist at Salonika to the 38th General Hospital with the rank of Major, R.A.M.C. (T.), and became X ray expert to the Scottish Command. In 1920 a lectureship in radiology was founded at the University of Glasgow and Riddell, who had some years previously been elected F.R.F.P. & S., was invited to occupy the post, which carried with it the appointment of physician in charge of the X ray department of the Western Infirmary, a post which he filled at the time of his death. He contributed to medical journals some practical essays on the employment of X ray methods in malignant disease and in uterine fibroids, and generally on the therapeutics of radium, and in 1927 he wrote a valuable handbook on medical electricity and radiology. The work was intended to inform the student mainly as to the employment of apparatus, but the general information on electrical therapeutics and reactions and the influence of X rays on living tissues were practical, and also very full considering the size of the work, while special attention was devoted to regional examination. Like so many of the early X ray workers Riddell suffered frequently from exposures, but he never allowed the amount or the character of his work to be interfered with, and must be regarded as one of the victims to scientific progress. The record of his energy supplied by his colleagues shows him to have been indefatiguable in his work and remarkably sympathetic in his attitude towards his patients, always very numerous, and many from the less fortunate classes.

JOHN MARSHALL DAY, M.D. Dub.

THE death occurred recently of Dr. John Marshall Day who had for many years been resident medical superintendent of the Cork-street Fever Hospital, Dublin. Born at Tuam, the son of Mr. Marshall Day, he received his preliminary education at the Diocesan school, Tuam, and the Rathmines school, Dublin, proceeding to Trinity College, Dublin, for his university training. He graduated as M.B., B.Ch. Dublin in 1885, took the diploma in State medicine three years later, and afterwards proceeded to the M.D. degree. His professional career largely centred round the Cork-street hospital, for shortly after graduation he received his first appointment in the institution as clinical assistant; later he was appointed a resident medical officer and finally became superintendent.

A Dublin correspondent writes: "Day speedily won a high reputation as an expert in infectious diseases and for many years enjoyed a large consulting practice in that branch of medicine. He was held in high esteem by the medical profession of Dublin, many of whom were brought closely into touch with him in his character of head of the principal fever hospital of the city. Further, it was his duty to give clinical instruction in fevers to the Dublin students. This he had done for the past 25 years, and there are several generations of students who must have been impressed by Day's clear clinical teaching and also have memories of his peculiar faculty for arriving at judgments without being able to communicate the reasons."

Outside his official work Dr. Day was particularly interested in medical organisation, was for a number of years on the committee of the Irish Medical Association, and was for two years president. He took his recreation in hunting and farming, and had retired from active work for several years.

NORMAN BRAITHWAITE, M.B., B.S. Durh.

THE death occurred on June 7th of Dr. Norman Braithwaite, the son of the late Mr. T. W. Braithwaite of Bishop Auckland, as the result of a motor-car accident. Born in 1894 he graduated as M.B., B.S. Durh. in 1917. He was then house physician at the Royal Victoria Infirmary, Newcastle, and served also as assistant in the out-patient department of the Royal Infirmary, Edinburgh. During the war he held a commission as captain R.A.M.C. (T.F.) He afterwards practised at Deeping, while for a period he made several voyages as a ship's medical officer. Recently he acquired a practice at Brackley and on settling down there married. His wife was with him when the fatal collision occurred. He leaves a widow and a baby, and the domestic circumstances made his death particularly tragic.

PUBLIC HEALTH

Paratyphoid at Ipswich

AT the present time 32 members of the medical, nursing, and domestic staff of the East Suffolk and Ipswich Hospital are in the borough isolation hospital with paratyphoid fever. These include 2 resident medical officers, 1 sister, 18 nurses, and 11 maids. These cases were admitted in the middle of June, when 2 other persons who can be connected with the East Suffolk and Ipswich Hospital were also admitted. At the beginning of June 6 cases of paratyphoid were taken into the isolation hospital, but it has not been possible to establish any connexion between these and the later admissions. So far it has not been possible to find a carrier or other source of infection for the East Suffolk and Ipswich Hospital cases, but full investigations are being made in association with a medical officer from the Ministry of Health who is on the spot. We understand that no cases have occurred in the county of Suffolk apart from the Ipswich ones.

An Attack on Maternal Mortality

A striking reduction in the number of deaths from childbirth in the Rhondda Valley was reported by Sir Julien Cahn, as chairman of the National Birthday Trust Fund, at its annual meeting last week. The special campaign began eighteen months ago: in its first nine months there were 29 maternal deaths (over 3 per month), in the next three months there were 6 (2 per month), and in the first six months of this year there have been only 6 more (1 per month), while the number of non-fatal septic cases has fallen in proportion. This result Sir Julien attributed to the wholehearted coöperation and untiring zeal of all those connected with the work, and especially of Dr. J. D. Jenkins, until recently superintendent of maternity and child welfare. Every help and encouragement has been given by the local authorities of the area and their medical representatives, and two district sister superintendents have been spared by Queen Charlotte's Hospital to act as assistant inspectors of midwives under the Rhondda council. Nearly half the practising midwives in the area have now taken advantage of the offer made by the Fund to take free refresher courses at the Royal Infirmary, Cardiff. This has been made possible for them by the payment of compensation for cases lost during their absence. The grant of 15*s.* compensation to those midwives whose cases are referred to hospital, on the advice of the medical officer of the antenatal clinics, has apparently been instrumental in removing local opposition, and the attendance at the clinics have nearly doubled in the last few months. Two firms have generously supplied large quantities of disinfectant to the Fund, for use in the Rhondda area, without charge. Sir Julien added that as it appeared that malnutrition was a contributory factor in certain cases, special foodstuffs, recommended by the medical committee, have been made available to 210 mothers in the districts of the Rhondda and Llantrisant to the value of about 2*s.* 6*d.* per week per mother. "It is interesting to note that the sharp drop in the death-rate has occurred since the introduction of this scheme, which we are hoping to be able to continue until the end of the year. This was made possible by the successful result of Mrs. Stanley Baldwin's special Food Appeal."

The reports on the first year's efforts in the Rhondda Valley area have been so encouraging that the Fund has undertaken to continue the scheme for a second year. It is felt that light is being thrown upon the problem of high rates of maternal mortality, and that a successful outcome of the work undertaken in the Rhondda Valley will have far-reaching results.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 22ND, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 1715; diphtheria, 847; enteric fever, 27; acute pneumonia (primary or influenzal), 702; puerperal fever, 36; puerperal pyrexia, 151; cerebrospinal fever, 15; acute poliomyelitis, 6; encephalitis lethargica, 7; dysentery, 7; and ophthalmia neonatorum, 103. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on June 28th was 2800, which included: Scarlet fever, 810; diphtheria, 1051; measles, 50; whooping-cough, 379; puerperal fever, 27 mothers (plus 7 babies); encephalitis lethargica, 269; poliomyelitis, 1. At St. Margaret's Hospital there were 20 babies (plus 10 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there were no deaths from small-pox or enteric fever, 23 (0) from measles, 5 (0) from scarlet fever, 20 (4) from whooping-cough, 23 (4) from diphtheria, 35 (13) from diarrhœa and enteritis under two years, and 35 (8) from influenza. The figures in parentheses are those for London itself.

Liverpool reported 5 of the deaths from measles, and West Bromwich 3 of those from whooping-cough. Of the fatal cases of diphtheria 3 were in Birmingham. Diarrhœa and enteritis caused 3 deaths in Liverpool and 2 each in Hull and Newcastle-upon-Tyne. There were 4 deaths from influenza in Birmingham, 4 in Manchester, and 2 each in St. Helens and Stockport.

The number of stillbirths notified during the week was 292 (corresponding to a rate of 41 per 1000 total births), including 45 in London.

OVERCROWDING OF HOSPITAL WARDS.—The Royal Victoria Infirmary, Newcastle-on-Tyne, has decided to limit the number of beds in the wards, and in future the number for which the building is designed (614) will not be exceeded.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Specialist Medical Treatment and Local Authority Control

ON the motion for the second reading of the Hertfordshire County Council Bill in the House of Commons on June 26th,

Sir MURRAY SUETER said that Part IV of the Bill dealt with establishments for massage and special treatment. The object was to save the public from being imposed upon by spurious practitioners who were very active in connexion with electrical treatment. He (Sir M. Sueter) could give the House an example of electrical apparatus being in improper and ignorant hands. When he was in H.M.S. *Benbow* at Portsmouth they were experimenting with X ray apparatus, and they had a Röntgen ray tube and a fluorescent screen. They used to take photographs of the torpedo lieutenant's hands, and as they were experimenting one day they thought they would like to see what was in the doctor's brain. They put the Röntgen ray tube in front of the doctor's brain and examined it through the fluorescent screen. They saw that the tissue of the brain was different and they were delighted with the examination. But in the morning when the doctor was combing his hair it came out in handfuls: he was perfectly bald on one side. They had destroyed all his hair on that side. The doctor was rather annoyed, but fortunately in a few weeks' time it had grown again and all was well. That was an example of the danger of such electrical apparatus being in improper hands. The promotors of the Bill sought to have powers to deal with this matter.

Dr. O'DONOVAN said that the purpose of the Bill had his heartiest concurrence, but he thought that certain aspects dealt with in Part IV ought to be made public so that the Committee which would examine the Bill could see what his profession was thinking of this Private Bill legislation which was affecting professional work. Bills very similar to this had gone through Committee before, and this measure appeared in its present form largely because that was the form in which previous Private Bills had been passed by Private Bill Committees. If Clause 48 and the consequent Clauses of this measure became enshrined once more in an Act of Parliament without a variation of its wording men and women who practised massage, manicuring, chiropody, electric treatment, radiant heat treatment, light treatment and vapour or other bath treatment, would be compelled to notify the chief of police of their intention to practise these special branches of bio-physical medicine. As Part IV stood without explanatory amplification he suggested that its imputations were offensive to a great body of useful people and bore no relation to the conditions under which they carried out their work to-day. He was entitled to say that, for since 1921 he had been a teacher, an examiner and a practitioner in this special part of medical treatment and he had not discovered that those whom he examined, those whom he taught, or those with whom he daily worked, were so undesirable that they should be subject to the attention of the county police.

Medical practitioners were given a certain freedom from the oppressive restrictions in Part IV, that was to say, it was not required that every medical practitioner should notify the police of his desire to practise special branches of medicine. But medical practitioners, perhaps London experts, who wished to practise in Hertfordshire any of these special branches of medicine, were required annually to produce from Hertfordshire practitioners a certificate that they were fit to carry out the special technique of their work. It would be a fair and appropriate observation to make that Hertfordshire, even in its county town, had not a panel of experts who were competent to certify as to the competence of experts who might go to practise there. It was strange that this county council should wish a certificate of special competence on the part of doctors who practised a very minor branch of medicine, and yet was not particular as to the special fitness of those who were to operate in more dangerous, more venturesome and more serious ways. Any practitioner in Hertford could deliver women in difficult labour without being required to prove his special competence to the Hertfordshire County Council, but should he install a mercury lamp or an X ray apparatus he became a suspected person who must year by year prove his fitness. Furthermore, nurses, specially trained and certified by the Chartered Society of Massage and Gymnastics, were to be under the same obligation of producing yearly certificates of their competence. Although a doctor or a specially certified massage nurse might become licensed in a simple way, nevertheless, the county council asked powers to pass by-laws instructing them how they should keep their records. Up to now a professional man had been entitled to keep his records and conduct his business in the way best suited to his personality, but this county council wished powers to pass by-laws so that his card index and professional records should be such as commended themselves to the council's advisers.

There was another point. The county council wished, properly or improperly, to set up a form of Medical Register of its own, for it not only asked those who practised these special forms of treatment to submit their technical qualifications, but it asked powers to set out in its own behalf what those qualifications should be. In other words, through this Bill and similar Bills there would be up and down England a multitude of minor quasi-responsible General Medical Councils. There were two incorporated societies of chiropodists in England who seriously taught their students, who trained them and examined them well, and granted them certificates, but the Hertfordshire County Council, without waiting for action at the hands of the Privy Council which was seeking to promote a Charter for the registration of chiropodists, would set up its own register of chiropodists; and then those who had successful boot shops and paid large rates could plant tame chiropodists in their back rooms and claim all the privileges of those who would benefit by registration at the hands of the Privy Council which could not be long delayed. That seemed to him to be a real wrong.

There was much professional feeling in this matter. They had heard from the member for Hertford (Sir M. Sueter) his experiences with X rays. Those experiences, inaccurately and wrongly reported, were nevertheless experienced at the hands of a registered medical practitioner, not at the hands of an undesirable person. Those experiments on a doctor's head, presumably with the doctor's consent and not under Admiralty orders, were carried out presumably by a registered medical practitioner. What ever dose of X rays the gallant Admiral gave to the doctor's hair that hair could not fall out the next day. It would take three weeks to fall out.

Sir M. SUETER: The next morning the doctor came down and told us that his hair had fallen out. When I said his hair grew again in a few weeks it may have been a few months, but it grew successfully and he did not have any bad effects afterwards, but it actually happened and I saw it. It was in the early days of X rays.

Dr. O'DONOVAN said he wondered if the gallant Admiral would take it from him that X rays in those days and X rays in these days would behave in exactly the same way. Their difference might be explained by the fact that when the Admiral was doing those experiments with X rays he (Dr. O'Donovan) was also doing them, but he had been doing them ever since, and the Admiral might be a little behind current medical practice. Nevertheless, the fact remained that X rays were a dangerous weapon in the hand of inexperienced or unskilled operators, but this clause in the Bill did not exclude in any way the use of X rays by anybody. It excluded electrical treatment or other similar treatment, and he and his professional colleagues would be pleased to go into any court of law and give expert evidence that X ray treatment and radium treatment, which was even more dangerous, were in no proper and strict use of the word electrical treatment or similar treatment. Any argument founded on Sir M. Sueter's experience was only an argument that this definition clause should be re-drafted, that expert advice should be more widely sought in this work, and that a county council should not put itself in a lamb-like manner into the hands of those who were professional parliamentary draftsmen.

The Bill was read a second time.

Diseases of Animals Bill

In the House of Commons on June 26th Mr. ELLIOT, Minister for Agriculture, moved the second reading of the Diseases of Animals Bill, which has already passed through the House of Lords. He said that the main objects of the measure were first, to bring poultry within the provisions of the Diseases of Animals Acts, and second, to provide for the regulation of the manufacture and importation of certain therapeutic substances intended for veterinary purposes. The provisions under which they were now made and sold were very unsatisfactory and representations had been made to the Ministry for some time by agricultural interests. A standard for one of these substances was recommended by the Cattle Diseases Committee of the Economic Advisory Council. The Bill would go to Committee where there would be full opportunity for examining it in detail.

Mr. T. WILLIAMS said that the Labour Opposition offered no objection to this Bill; they thought it was very useful.

The Bill was read a second time and committed to a Standing Committee.

Health Services and Housing in Scotland

On Friday, June 28th, the House of Commons went into Committee of Supply on the Scottish Estimates. Captain BOURNE, Deputy Chairman of Committee, was in the chair. On a vote for £2,062,724, to complete the sum necessary to defray the charge for salaries and expenses of the Department of Health for Scotland, Mr. SKELTON, Under Secretary of State, pointed out that the health of the nation had never been so good, improvement being manifested in every direction save maternal mortality, where there had been a slight rise compared with last year, although it was about the same as the average of the last five years. A report on maternal mortality which had long been subject to anxious examination by experts, would, he said, be published in a few days, and was of a more intensive and exhaustive character than any previous examination of the question in either England or Scotland.

The Public Health Services Committee, which was appointed last year by the Secretary for Scotland, was carrying on its work with great energy and vigour, although he regretted to say that the chairman, Sir John Dove-Wilson, unfortunately died quite recently. He had been succeeded by one who would, he thought, command respect and approval in every section of the community, namely, Prof. Cathcart of Glasgow.

Dealing with the progress of housing Mr. Skelton said that the number of houses completed in 1933 numbered 20,915, but then, of course, subsidies to private enterprise were still going strong and there was not the same concentration on slum clearance. Of that figure of 20,915 houses 15,000 were local authority houses, and the balance were private enterprise houses. Last year the total was 18,417, 14,700 being local authority houses and 3,600 private enterprise houses. The most recent figures of completions showed that they were again increasing the numbers. In the first five months of 1934 6056 houses were completed, and in the first five months of this year 6,500, an increase of practically 500. On a rough estimate he believed that the local authorities completions, which were 14,719 for last year, might be in the neighbourhood of 17,000 for next year. They had this year the highest number of local authority houses under construction that there had ever been. At the end of May this year there were 18,119 local authority houses under construction, whereas in May last year there were only 14,488, and in the year before 17,035. Most striking of all was the progress of slum clearance under the present five-year plan, which began on Jan. 1st, 1934. The local authorities estimated their needs over the period to be 61,316 houses. The actual further building programmes submitted provided for 47,900 houses, or 78 per cent. of the total. Many of the local authorities had undertaken that if it was possible they would increase their programmes to such an extent that 92 per cent. of the needs would be undertaken in the five years. Mr. Skelton concluded by giving the figures dealing with the tenders for new houses which proved the skill and energy with which Scottish Local Authorities as a whole had undertaken the work dealing with the slums.

At the middle of June, 17½ months after the beginning of the five-year plan, tenders had been approved for 30,681 houses out of the 47,900, and of the 30,000 odd tenders approved only 6000 represented houses which had not been either begun or completed. That showed the zeal and energy with which the Scottish local authorities as a whole had undertaken the work of dealing with slums in the course of this new period. The momentum with which slum clearance was being tackled showed no signs of slackening. No tenders were being approved for two-room houses, and a very considerable proportion of the tenders were for four-room and some for five-room houses. Under the provision in the Rural Workers Act the reconditioning of farm cottages went steadily on. In the vast majority of cases of people removed from slums there was immediate and strong response to the improved conditions. It was also true that in the sphere of health the population of Scotland was increasingly responsive to the efforts that were made by public health authorities. Maternity and child welfare centres were constantly increasing in popularity.

Sir A. SINCLAIR said that they were glad to know that, broadly speaking, the health of the people of Scotland was good and was improving, but it still remained true, as was pointed out in the annual report of the Department of Health, that the public demand for hospital treatment was increasing. Unfortunately this demand was not being met. In regard to hospital services the report said:

> "Recently a study was made of the records of a large number of consecutive patients admitted to the medical wards of one of the best of our general hospitals. It was found that many of them had been ill for months or years prior to admission. Pressure on bed accommodation was so great that the duration of in-patient treatment had to be kept as short as possible. Only 26 per cent. of the patients reviewed remained in hospital for more than one month, and only two per cent. for more than three months. It is not surprising, therefore, that on discharge from the hospital more patients were classified as 'relieved' than as 'cured'." The report added: "It is impossible to regard such results with equanimity."

This was a serious matter and it was impossible to regard the condition of the hospitals in Scotland with equanimity. He would ask the Government to state what they were doing to remedy the state of affairs. A doctor who had returned after a number of years in the Malay States to take up an appointment in Scotland recently, told him that the hospital services in Scotland were inferior to those in the Malay States. He (Sir A. Sinclair) was incredulous, but this doctor's opinion was not inconsistent with the stern and sombre warnings addressed to the local authorities in the report of the Department of Health. At the present moment there was no more serious need under the heading of public health in the Highlands of Scotland than an increase in the water-supply. He impressed on the Government the vital importance of that cardinal requirement.

Sir IAN MACPHERSON, in regard to the Highlands and Islands Medical Service, said that it was not economy and had not been the original intention to transport patients from the islands to a central hospital, while he disagreed with Sir A. Sinclair in regard to the superiority of hospitals in Malay over those in Scotland.

Sir CHARLES MACANDREW, on the question of maternal mortality in the report of the Department of Health, said:

> "The total number of midwives enrolled by the Central Midwives Board for Scotland since the roll was established in 1915 up to the 31st March, 1934, was 11,002, of whom 7440 were enrolled after passing the Board's examination."

That perhaps might account for the rate of maternal mortality. It seemed extraordinary that over 3500 midwives who could not pass the examination should be on the roll. Midwives who could not pass the examination, but who were nevertheless on the roll, might do enormous damage to health in Scotland. Referring to venereal diseases the report said:

> "In the absence of any system of notification the incidence of venereal diseases in the country is unknown."

It might be that legislation was required to make it notifiable. The report said:

> "Infected mothers often show great anxiety for the health of their children and bring them willingly to the centres for observation, and for treatment if necessary. In one or two areas, also, infected parents have been persuaded to allow their children to be admitted to hospital for intensive observation."

Was it not possible to make it compulsory for doctors to notify these cases? Then there was the question of the teeth of the children. The dental staffs consisted of 48 whole-time and 35 part-time dentists, and the report said:

> "It is very doubtful whether the existing dental staffs can adequately supervise the condition of the teeth of the children, especially since much of their time is occupied in attending to casual cases, that is, children suffering from tooth-ache whose teeth may be beyond saving."

If a little of the money which ought to be saved on other things could be devoted to the dental service it would be of great benefit to the children. It was most regrettable to learn that at this age the teeth of many children were beyond saving. Anyone who had had an opportunity of seeing the holiday camps must be aware that the sanitary conditions were anything but satisfactory. He suggested that it might be a desirable thing if some of the medical officers attached to territorial units were allowed to inspect these holiday camps because they had much more experience of camps than the officials of the Department of Health.

Mr. MAXTON said that he was interested to know that the number of persons who had to apply for poor relief per thousand of the population in Scotland in 1934 was precisely the same proportion as had to apply in 1867. That was rather a distressing figure. It showed that over a period of 70 years there had been no substantial change made in the ratio of very poor people to the total population. He also found that the cost in one district of maintaining the poor in poor-law institutions—the sick poor, the able-bodied poor, and the insane poor—fell as low as 5s. a week. That was an appalling figure. Above that figure of 5s. a week there were all sorts of variations. He was sure that for the money that it had cost to keep poor people in poor-law institutions in Scotland in general there could not be inside those institutions the amenities of life that were certainly made possible by the Scottish Poor Law Act which was recently passed. He hoped the Government would inquire whether the local authorities were in fact operating the new Poor Law Act in the way that he believed and hoped that it would be operated.

Dr. G. A. MORRISON raised the question of the reports of the medical officers of schools with reference to the large number of children who on coming to school were found to be suffering from easily remediable defects. The inspectors of the English Board of Education used this as one of the strongest arguments for the institution of more nursery schools, especially in the large cities. His wife, in connexion with her experience in a girls' club in Aberdeen, had been struck by the number of girls of 17 and 18 years who had very bad teeth, and in some cases almost no teeth at all. The gap between the time when boys and girls received skilled dental attention at school and the time when they were due to receive dental benefit from some approved society would be to some extent closed if there was an extension of the provision of dental attention to the junior instruction centres.

Mr. SKELTON, replying to points raised in the debate, said the question of the provision of hospitals, which had been mentioned by Sir A. Sinclair, was one on which the Government could not interfere with the local authorities. The 1929 Act increased facilities for proper hospital accommodation by making it easier for local authorities to combine for the purpose of hospital building and maintenance. He regretted to say that it had not always been taken advantage of, and while he agreed that progress had been slow, he did not propose to relax pressure on local authorities to get on with the work of hospital accommodation wherever it was insufficient. He entirely agreed with the observations in the report of the department that much required to be done before the matter could be regarded as satisfactory, and that would be borne out, he thought, by the maternal mortality report, but under existing legislation, apart from exerting pressure on local authorities, there were no substantive steps which the Secretary of State or he could take on this topic of the supply of hospitals. He could assure the committee that the Government would not forget the question of Highland water-supplies. In regard to the employment of unqualified midwives, it was not possible to apply the provisions of the last Act to persons who were midwives when the Act came into operation. The question of dental service again was primarily a matter for the local authorities. With regard to camps and their sanitation, local authorities already had considerable powers in making by-laws for the control of such camps.

Further discussion of the Note was adjourned.

Voluntary Hospitals (Paying Patients) Bill

The Voluntary Hospitals (Paying Patients) Bill and the St. Bartholomew's Hospital Bill were brought down from the House of Lords and read a first time in the House of Commons on Monday July 1st.

University of Durham Bill

In the House of Lords on Tuesday, July 2nd, the University of Durham Bill was read the third time and passed.

Housing (Scotland) Bill

The Housing (Scotland) Bill passed the Report stage in the House of Commons on Tuesday, July 2nd. The Public Health (Water and Sewerage) (Scotland) Bill and the Criminal Lunatics (Scotland) Bill were read a second time.

HOUSE OF COMMONS

THURSDAY, JUNE 27TH

Workmen's Compensation Inquiry

Mr. TOM SMITH asked the Home Secretary if he was in a position to make a statement with regard to the inquiry taking place into the working of the Workmen's Compensation Act.—Sir JOHN SIMON replied: A general inquiry into every aspect of the working of the Workmen's Compensation Act would be a large undertaking, which would take up much time, but I have been considering whether there are not some specific questions which could be more speedily examined, and I hope it may be possible to make a statement on the subject very shortly.

Mr. Smith: Will the right hon. gentleman keep in mind the specific question which was sent to his predecessor by the Miners' Federation of Great Britain relating to a legal decision with regard to miners' nystagmus?

Sir J. Simon: One of the specific matters which I had in mind when I gave my answer was the case of miners' nystagmus.

Physical Training in Schools

Mr. Hall-Caine asked the President of the Board of Education in what approximate proportion of primary and secondary schools, respectively, at the present time, physical training was carried out in special costumes as opposed to the ordinary clothes of the pupils; and in what proportion the physical training of boys was superintended by male instructors.—Mr. Stanley replied: I regret that the information in my possession does not enable me to reply to the first part of the question. The provision of special costumes for physical training is encouraged by the Board and is becoming more general. I have no information as to the proportion of schools in which boys are taught by male instructors. In elementary schools the instruction is given by the class-teachers, who in the case of senior boys' departments would be men; in boys' secondary schools there is generally a male instructor on the staff.

Care of Deaf Persons

Mr. Hutchison asked the Minister of Health whether he proposed to introduce or give facilities for a Bill dealing with the disability of deafness; and whether he was satisfied with the adequacy of present arrangements for the care of such persons.—Sir Kingsley Wood replied: I am not at present satisfied that special legislation on this subject is necessary. My hon. friend is no doubt aware of the report prepared by the late Dr. Eichholz on the condition of the deaf. That report did not recommend any further legislation, but advocated certain measures which were commended to local authorities in a circular issued by my department in May, 1933. The Ministry are continuing to impress on local authorities the importance of giving financial assistance, where necessary, to those voluntary agencies which are doing valuable work in finding suitable employment for deaf-and-dumb persons.

Mortgage of Insurance Medical Practices

Mr. Logan asked the Minister of Health if he was aware of the mortgaging and transfer of medical practices in connexion with panel patients controlled by financial houses; and if he was prepared to investigate this matter.—Sir Kingsley Wood replied: My attention has been drawn to arrangements by which medical practitioners are able to obtain loans on the security of their income from insurance practice; but in the absence of specific evidence that these arrangements are exercising a prejudicial effect on the insurance service, I do not think this is a matter in which it would be proper for me to intervene.

Mr. Logan: Is the right hon. gentleman aware that I did send him a press cutting in which definite statements were made and will be make investigations into this matter?

Sir K. Wood: It is difficult for me to begin to examine statements in the press. If the hon. Member has any particular facts of his own knowledge I shall be glad to have a talk with him about them.

Mr. Rhys Davies: Will the right hon. gentleman be good enough to look at the report sent to his predecessor by the Association of Insurance Committees on this subject?

Sir Francis Fremantle: Is it not a fact that patients always have a choice of doctor and therefore they cannot be sold except from the point of view of goodwill and subject to the wish of the patients?

Cost of Milk to Hospitals

Mr. Graham White asked the Minister of Agriculture if any estimate had been made of the additional cost of milk to voluntary and other hospitals since the Milk Marketing Board was instituted; and if the Board and/or the Government proposed to take any action to relieve the hospitals of this additional burden.—Mr. Elliot replied: I would refer the hon. Member to the replies I gave on May 2nd, to which at the moment I have nothing to add.

Mr. T. Williams: Will the right hon. gentleman make representations to the Milk Marketing Board on the question of granting hospitals and such institutions treatment similar to that received by ice-cream vendors?

Mr. Elliot: It is difficult to suggest that a certain class of individuals should bear the loss on the supply to hospitals unless it is suggested by the people who supply hospitals.

Mr. Williams: Is the right hon. gentleman aware that the consumers and the producers as the case may be are really bearing a large loss on milk sold to ice-cream vendors?

No answer was given.

Child Labour in the Fields

Mr. Burnett asked the Secretary of State for Scotland how many local authorities used the powers given to them under the Children and Young Persons (Scotland) Act, 1932, to restrict or prohibit child labour in the fields.—Mr. Skelton, Under-Secretary of State for Scotland, replied: No education authority in Scotland has taken power by by-law, under the Act mentioned, to prohibit entirely the employment of children in agricultural pursuits. In five areas the statutory minimum age for employment of 12 years has been raised by by-law to 13 years for all employment, including agricultural work, though in one of these areas the higher age limit applies only to girls. Thirty-three of the 35 education authorities have made by-laws as to the employment of children, and in each case the by-laws include provisions for regulating the hours and conditions on which children may be employed.

MONDAY, JULY 1ST

National Health Insurance Appeal

Mr. Lunn asked the Minister of Health whether he would give the reason for the delay in not setting down for appeal to the High Court the case of Mrs. K. Slaughter, of 112, Brentwood-road, Romford, Essex, against the decision of the referee appointed under Section 90 of the National Health Insurance Act, 1924.—Mr. Shakespeare, Parliamentary Secretary to the Ministry of Health, replied: The Referee appointed under Section 90 of the National Health Insurance Act, 1924, acceded to the request of Mrs. Slaughter to state a case for the decision of the High Court on a question of law. There has been some unavoidable delay but my right hon. friend is informed that the terms of the case have now been settled and signed by the Referee and forwarded to Mrs. Slaughter's solicitors, who are, therefore, now in a position to set down the case for hearing.

Lung Trouble among Barytes Miners

Mr. Duckworth asked the Secretary for Mines whether his attention had been drawn to the frequent occurrence of lung trouble among barytes miners and quarrymen in the Minsterley and Pontesbury district of Shropshire, and in particular to the death from silicosis of John Richards, of 9, Top-road, Pontesbury Hill, on May 21st; whether His Majesty's inspectors of mines had inspected and reported upon the conditions under which work was carried on; and whether he was satisfied that every possible precaution was being taken to safeguard the workers from this danger.—Captain Crookshank replied: I have received no information of cases of industrial pulmonary disease in this district except at one barytes mine: and at this mine proper precautions are being taken following a thorough inspection of the conditions by H.M. Inspectors of Mines. The case of John Richards has not previously been brought to my notice and I am having it investigated.

Accidents in the Building Trade

Mr. JOEL asked the Home Secretary whether any information had been laid before his department to show that accidents in the building trade were increasing; and whether insurance companies were now making exhaustive inquiries as to the cause.—Sir J. SIMON replied: If the figures for the last five years be compared there would not appear to be any material change in the proportion of accidents in this trade, and I am advised that the increase in 1934 over 1933 may be fully accounted for by increased building activity and by better reporting of accidents to the need for which the special attention of employers was recently drawn. It has, however, been recognised by my department for some time past that the situation calls for further inquiry and I have just appointed Mr. G. S. Taylor, Deputy Chief Inspector of Factories, specially assisted by three other inspectors, to make a report, after consultation with bodies concerned and after any necessary inquiries, reviewing the accident risks in the building industry and the precautions already adopted, whether by way of regulations or otherwise, with a view to advising as to what further measures may be desirable.

Infection of Workers Due to Paint Spraying

Mr. JOEL asked the Home Secretary if the information in his department showed that there was any increase in infection of workers due to paint spraying.—Sir JOHN SIMON replied: I have no information indicating any increase of illness from this cause.

Accidents Due to Electrical Apparatus in Private Houses

Mr. TEMPLE MORRIS asked the Home Secretary how many fatal accidents there were during 1934 from the use of electrical apparatus in private houses; and whether he was satisfied that existing legislation was sufficient to prevent the sale of articles which could not be used with safety by inexperienced persons.—Sir JOHN SIMON replied: Accidents from the use of electrical apparatus in domestic premises are not reportable to the Home Office, but fifteen fatal accidents of this kind came to the notice of the department during 1934. The law does not prohibit the sale of electrical appliances on the ground that they may be dangerous to inexperienced persons, but only a few instances have come to the notice of the department in which exception could reasonably be taken, on grounds of danger, to electrical apparatus placed on sale, and in such cases manufacturers generally have shown themselves ready to remedy the defects, when pointed out to them.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A course in urology will be given at the All Saints' Hospital from July 8th to 27th; it will occupy the afternoons and evenings with clinical and cystoscopic demonstrations. A week-end course in general medicine and surgery is to be held at the Southend General Hospital on July 13th and 14th, and an afternoon course in Dermatology at the Blackfriars Skin Hospital from the 15th to 27th. A panel of teachers who are prepared to give clinical instruction at their in-patient and out-patient clinics is prepared by the Fellowship. Particulars may be had from the Secretary at 1 Wimpole Street, London, W.1.

WESTMINSTER HOSPITAL.—On June 26th the Prince of Wales laid the foundation-stone of the nurses' home which is to be the first building of the new Westminster Hospital. As recounted in our issue of June 22nd, the new building is to be erected on the west side of St. John's Garden's, not far from Lambeth Bridge, and will accommodate 40 sisters, 200 nurses, 15 pupils undergoing preliminary training, and 50 domestic staff. It was announced that Mr. Myerstein has presented a cheque for £10,000 for the medical school building.

BRITISH POSTGRADUATE MEDICAL SCHOOL

THE FIRST REFRESHER COURSE

A COLLECTION of practitioners of different ages and widely varying experience assembled for the first intensive refresher course held at the British Postgraduate Medical School from June 17th to 29th, only a month after the school was formally opened. The staff of the school was supplemented on this occasion, and will be also in the future courses, by outside specialists, this time represented by Dr. C. W. Buckley, Dr. L. S. T. Burrell, Dr. E. Mapother, and Dr. J. A. Ryle. The sessions on each day were from 10.30 A.M. to 1 P.M., and 2 to 4.30 P.M., with fifteen minute intervals in the course of each morning and afternoon.

FIRST WEEK

Dr. F. R. Fraser, professor of medicine, welcomed the students with what was described by one of them as a "really refreshing preamble which justified the title of the course." He spoke sympathetically of their common experience of the many psychological problems which block the way to success in many cases which should be curable. The part played by psychic trauma in general structural disease is, he holds, a major one. The practitioner has it in his power to increase the health and happiness of mankind and to treat the individual (not the mass) to be better fitted for his environment. He must remember that the governing motive that takes the patient to the doctor is fear—fear in relation to his life or to his efficiency. It is prognosis that he wants, and this necessarily implies diagnosis, not merely anatomical diagnosis, but a realisation of the actual disease process and the stage it has reached. Prof. Fraser discussed the determination of the data involved and emphasised the value of history-taking as against mere physical examination. Whilst history-taking is subjective and symptomatic, physical examination is objective and structural. The majority of medical out-patients have no objective physical signs, but if they have it is criminal to miss them. The patient must be investigated as a biological entity in order to discover his environment, and the cause of his possible misfit in life. In the elaboration of this detective game questions on past health rather than on the more familiar past illnesses are important—e.g., "did you play games?" Two case-histories were detailed, one of a clergyman and the other of a girl clerk, to illustrate the importance of digging out the psychological basis of disease in spite of an apparently obvious anatomical diagnosis. Prof. Fraser doubted, rather wickedly, if Harley-street could live, given on the part of each medical practitioner the gift for good history-taking and a more highly developed faculty for using the eyes.

With these encouraging words, which established a friendly understanding, Prof. Fraser passed on to a demonstration of his own methods of physical examination on a variety of interesting cases.

In the afternoon Dr. Burrell followed with a rapid but fairly exhaustive survey of the main problems of pulmonary tuberculosis. Among the lessons to be drawn from his teaching were that in diagnosis symptoms are more reliable pointers than physical signs, which may be absent; that a differential leucocyte count and an estimation of erythrocyte sedimentation-rate may have prognostic significance;

and that senile tuberculosis is far more common than is generally believed. He discussed treatment at the stage of attack, at the stage of defence, and when the patient is discharged from a sanatorium, giving indications for and against the various modern surgical measures.

The next day was devoted to visits in the morning to the Central London Throat, Nose and Ear Hospital, and in the afternoon to the London School of Dermatology, St. John's Hospital for Diseases of the Skin.

Wednesday was given up to a symposium on gastric ulcer. Dr. Ryle started with a lecture on the natural history of peptic ulcer, the commonest organic cause of dyspepsia in males and a prominent cause of sick-wastage. Duodenal ulcer alone supplies 1 per cent. of admissions to a large general hospital. Many more are treated as out-patients, still others do not come to hospital, and many escape diagnosis. It is a disease with low mortality, but deaths in this country in 1930 are twice the numbers of those for 1920. Owing to lack of physical signs and other causes, diagnosis is commonly missed or delayed, and the spontaneously relapsing course of duodenal ulcer with long free periods is also a reason for missed diagnosis. In a long series of cases the average duration of a duodenal ulcer prior to diagnosis was seven years. The precise mode of causation remains obscure. The symptomatology of duodenal and gastric ulcer and their complications were discussed. Prognosis depends on age or stage of ulcer, age and occupation of patient, and presence or absence of complications. In assessing the choice and prospects of treatment length of history is especially valuable. The earlier the diagnosis the better the prospects of medical relief. After this lecture demonstrations were given of pathological specimens by Prof. E. H. Kettle, of patients by Dr. Ryle, and of the tests for occult blood in stools by Mr. E. J. King, D.Sc. After lunch Dr. Duncan White gave a lecture-demonstration on the place of radiology in the diagnosis and management of peptic ulcer, and Dr. Ryle discussed the functional dyspepsias and their differentiation from ulcer dyspepsia, and detailed the treatment of peptic ulcer with a demonstration of diets during the first month of treatment.

On Thursday morning Dr. Janet Vaughan explained the differential diagnosis and treatment of common types of anæmias. She classified the anæmias on an ætiological basis, detailed the essential hæmopoietic factors, and described the out-patient diagnosis of deficiency anæmias by a combination of clinical and laboratory methods. The fact that the response of deficiency anæmias to treatment is specific was emphasised and the possible presence of a dual deficiency in certain cases discussed. While iron must be given by the mouth, deficiency of the pernicious anæmia (P.A.) factor is most effectively and cheaply dealt with by parenteral therapy. In the afternoon Sir Frederick Banting lectured on the history of insulin and Prof. J. Young gave a demonstration of obstetrical cases.

On Friday Prof. Young, in the course of a lecture on antenatal examination, pointed out that 10 per cent. of maternal mortality is due to ante-partum hæmorrhage, and 18 per cent. of maternal mortality is, in normal cases, due to sepsis. Morning sickness might be attributable to night starvation. If it was very severe salines per rectum brought relief. In the afternoon Dr. Chassar Moir discussed some common gynæcological conditions, showing cases of prolapse and of dysmenorrhœa. He pointed out the importance of preventing a mother from being over-sympathetic with a girl suffering from dysmenorrhœa. In his experience glandular preparations had been of little help in such cases, but in severe cases of dysmenorrhœa unrelieved by other methods a presacral sympathectomy had proved successful.

On Saturday Dr. Mapother, speaking on psychiatry in general practice, showed cases to illustrate the association between arterio-sclerosis and mental disorder. He dealt also with the differential diagnosis of neurosis and psychosis, pointing out that in neurosis the patient is not detrimental to others and has insight into his condition.

SECOND WEEK

Prof. G. Grey Turner started the second week with a lecture on gastric carcinoma, its diagnosis and treatment. He emphasised the importance of repeated clinical examinations, test-meals, and examinations of vomit for blood. The mortality of gastrectomy was 10 per cent.; when there was probability of gastric carcinoma, the risk of abdominal exploration was less than the risk of delay. Prof. Grey Turner detailed the operative treatment and Dr. Duncan White demonstrated X rays of the condition.

In the afternoon Prof. Fraser lectured on heart disease and heart failure, its diagnosis, treatment, and prognosis. Tuesday was spent profitably at the Hospital for Sick Children, Great Ormond-street. On Wednesday Dr. Buckley lectured on chronic arthritis of the rheumatoid and osteo-arthritic types, showing the pathological, and, with Dr. White's help, the radiological features peculiar to each type, and in the afternoon spoke of the chronic rheumatic affections, notably sciatica (trunk, root, and referred); spondylitis (ankylosis and osteo-arthritic), and lumbago. On Thursday Dr. J. G. Scadding dealt with some common respiratory diseases, devoting most time to bronchiectasis and pulmonary suppuration and to asthma. In the afternoon Mr. Lambert Rogers, speaking on fractures, drew attention to a general simplification in methods of treatment. The multitude of splints formerly in use had disappeared and plaster-of-Paris was increasingly popular. There was also a decline in operative treatment, except in certain fractures, and a tendency towards longer periods of immobilisation. Next morning Mr. Lambert Rogers lectured on head injuries and in the afternoon Prof. Grey Turner gave an address on the diagnosis of acute abdominal conditions, showing how acute appendicitis in its different forms (without peritonitis, with local peritonitis, with flank or pelvic peritonitis or both, and with residual abscess,) could be differentiated from acute gall-bladder, perforation of gastric or duodenal ulcer, and intestinal obstruction. On the last day of the course a demonstration of local anæsthesia was given and the members of the class were given an opportunity for making critical and constructive suggestions on the requirements of a refresher course of this kind.

CONCLUSION

The first venture of this new school was accounted a real success. The brief impressions noted above were collected from various members of the class and are not a balanced summary of the salient features but an indication of the practical nature of the instruction provided. The course coincided with a spell of hot weather and arrangements had not yet been made for electric fans or other devices to mitigate the heat in the lecture theatres. The disadvantage of having these in close proximity to the hospital was sometimes apparent, since noises from the out-patient department and from patients' friends on visiting days were occasionally disconcerting

On the other hand, the fittings of the demonstration theatre, the excellent epidiascope, and the arrangement whereby the lecturer can communicate by microphone with the technician outside the theatre who is showing his slides were most convenient. The school has made a good start with these short pithy courses. We understand that the later ones to be held from July 15th to 27th, Sept. 16th to 28th, and Nov. 18th to 29th have been planned on much the same lines.

MEDICAL NEWS

University of Oxford

At recent examinations the following candidates were successful :—

Materia Medica and Pharmacology.—E. J. S. Barthorpe, R. Billig, R. G. Blackledge, L. B. Bok, J. F. Bourdillon, T. N. Branch, R. C. Browne, F. G. Ethiraj, A. W. Frankland, T. Gadian, W. M. Gibson, S. R. Gloyne, N. J. S. Gurney, J. C. Hewetson, J. R. Hollick, R. M. Hugo, A. M. L. Isabella, E. L. James, P. R. W. Leigh, J. N. Mills, R. G. W. Ollerenshaw, H. G. O. Owen-Smith, J. A. Partridge, C. W. R. Rayne-Davis, I. F. Rose, T. B. Snell, N. E. Stidolph, S. F. Taylor, G. J. Walley, J. Walter, C. M. F. Walters, D. Whitteridge, W. Wynne Willson, and W. B. Young.

Pathology.—W. D. Brinton, R. C. Browne, W. W. Coppinger, P. S. Edgecombe, A. F. Foster-Carter, D. B. Fraser, W. E. Gibb, S. R. Gloyne, C. F. Hamilton-Turner, G. F. C. Hawkins, J. C. Hewetson, J. H. Lewis, N. H. Martin, H. Muller, C. I. Murphie, T. E. Ooi, H. M. Sinclair, D. H. Swayne, R. Y. Taylor, A. L. Watson, and A. L. Young.

Forensic Medicine and Public Health.—P. C. Alexander, W. J. C. Anstie, D. R. Balcombe-Brown, P. S. Buckley, M. C. Chapman, H. N. Davis, H. Fidler, W. E. Henley, G. A. Hodgson, J. R. Hollick, J. F. Loutit, W. P. Mallinson, A. P. Meiklejohn, R. Passmore, F. R. P. Pepper, H. Rees, and F. G. Ward.

Medicine, Surgery, and Midwifery.—W. J. C. Anstie, N. E. R. Archer, R. Bevan, P. G. Burgess, H. Burton, M. C. Chapman, C. D. Coode, P. E. Cresswell, K. B. Dawson, C. F. Hamilton-Turner, W. E. Henley, D. H. Hertz, J. R. Hollick, C. Hollins, N. Leitch, A. P. Meiklejohn, D. F. G. Moir, J. C. Penton, T. W. H. Porter, K. C. Royes, W. R. Trotter, and J. W. A. Turner.

University of Cambridge

On June 22nd the following degrees were conferred :—

M.D.—R. A. Ratcliff and F. J. Wright.
M.Chir.—R. J. V. Battle.
M.B. and B.Chir.—C. J. G. White.
M.B.—W. H. Gabb.
B.Chir.—W. S. Haynes.

University of Durham

On June 27th the honorary degree of doctor of civil law was conferred on Prof. Thomas Beattie and the honorary degree of doctor of surgery (D.Ch.) on Prof. G. Grey Turner. Ordinary degrees and diplomas were conferred as follows :

M.D.—E. Browell, G. Davison, W. Foskett, J. J. H. Lowe, F. McGuckin, G. M. Miller, J. A. Stobbs, F. H. Taylor.

M.D.S.—A. D. Hitchin.

M.B. and B.S.—B. M. Axton, C. Bainbridge, H. H. S. Brown, J. Cleminson, T. A. Cockburn, W. Cowell, R. J. Crompton, H. R. Dewar, A. K. Dougall, W. Dunn, H. Fabricant, J. F. Fraser, V. E. Gillis, N. D. Gofton, W. F. Hall, J. G. H. Harbinson, T. E. Henderson, J. R. Heslop, N. Q. Hesse, T. F. Hird, A. S. Jarman, H. L. Jenkins, D. C. Morris, A. H. G. Munro, L. H. Murray, A. E. Paxton, D. Reemer, K. D. Rosner, R. J. Rutherford, M. Salpeter, G. H. Scott, J. N. Swainston, J. Swinney, J. V. Todd, H. Weiss, G. H. Whalley, and S. Woolf.

B.Hy.—J. Angus, D. S. Buchanan, and N. V. Hepple.

D.P.H.—J. Angus, D. S. Buchanan, and N. V. Hepple.

L.D.S.—L. R. Bowlby, A. S. Douglas, R. M. Stephenson, and C. J. Thubron.

University of Glasgow

Mr. John Adam Gib Burton has been appointed to succeed Prof. Peter Paterson in the St. Mungo chair of surgery in the university.

Mr. Burton, who is surgeon to the Glasgow Royal Infirmary, graduated at Glasgow in 1909, and saw active service during the late war in France, Gallipoli, and Mesopotamia, receiving the Military Cross. He was formerly lecturer in pathology, but subsequently became Prof. Paterson's senior assistant, and is at present hon. lecturer in clinical surgery in the university.

On June 28th the following degrees were conferred :—

D.Sc.—Tudor Jenkyn Jones, M.B.

M.D.—John Wyllie (with high commendation), J. L. Dunlop (with commendation), and A. F. R. Dewar (in absentia).

A Congress on Gout

From Sept. 14th to 16th a conference will be held at Vittel, in France, on the subject of gout and uric acid. Those taking part will include Prof. Loeper, Prof. Fiessinger, Prof. Rathery, Prof. Marcel Labbé, Prof. Villaret, Prof. Étienne, Prof. Santenoise, Dr. M. P. Weil, Prof. Pasteur-Vallery-Radot, and Dr. A. P. Cawadias. The foreign committee includes (in this country) Dr. Cawadias and Sir William Willcox. Particulars may be had from Dr. M. Boigey, secrétaire général du Congrès de la Goutte, Vittel, Vosges.

University of Edinburgh

On June 28th the honorary degree of doctor of laws was conferred on Surg. Commander J. D. Pollock.

The degree of Ph.D. was also conferred on Dr. Munir El Gazayerli.

University of St. Andrews

The honorary degree of LL.D. has been conferred on Dr. C. H. Browning, F.R.S., Gardiner professor of bacteriology in the University of Glasgow, and Sir John Boyd Orr, M D., F.R.S., director of the Rowett Institute for Research in Animal Nutrition, Aberdeen.

Middlesex Hospital Medical School

The council of the Middlesex Hospital medical school has decided to celebrate the hundredth anniversary of the foundation of the medical school on Wednesday, July 24th. In the afternoon the prizes and medals won during the session 1934–35 will be presented to students by the Chancellor of the University of London, and on the same date there will be a scientific evening. Both ceremonies will be held at the Middlesex Hospital. The students' centenary ball will take place at the Dorchester Hotel on the evening of July 25th. The "refresher course" and annual dinner will be held as usual during the last few days of September and early in October respectively.

Tribute to Mr. Webb-Johnson

On June 27th Mr. A. E. Webb-Johnson, F.R.C.S., surgeon to the Middlesex Hospital, was entertained to dinner at Claridges Hotel by members of the hospital board, medical staff, and medical school. The dinner was given on the completion of the new Middlesex Hospital, to show appreciation of Mr. Webb-Johnson's work during the past ten years. He has been chairman of the plans committee from the beginning and has, it is stated, been responsible, directly and indirectly, for raising £500,000 of the £1,250,000 which the scheme has cost.

Metropolitan Water Board

Dr. Donald Craig Norris, F.R.C.S., deputy medical officer of the Bank of England, has been appointed chief medical officer of the Metropolitan Water Board in succession to the late Sir John Collie.

Hertford Hospital, Paris

An English resident in Paris has offered to give £1360 towards the special fund for alterations and additions to this hospital, provided three others will give the same. It was founded and endowed by Sir Richard Wallace for the treatment of poor British subjects and was opened in 1879. Until 1920 nobody was asked to contribute to the funds, but the drop in the exchange value has made it necessary to appeal for help.

Hospital of St. John of Jerusalem

The King has sanctioned the following promotions in and appointments to the Venerable Order of the Hospital of St. John of Jerusalem :—Knights of Grace : Lt. Col. Sir Louis E. Barnett, Dr. I. G. Modlin, Major J. Orton. Commanders : Dr. W. G. Rogers, Surg. Lt.-Col. E. J. H. Luxmoore, Lt.-Col. G. E. Peacock, S. S. Pringle, P.R.C.S.I., Dr. Ian Fraser. Officers : Dr. C. H. Perram, Dr. H. L. Garson, Dr. H. R. Richard, Dr. O. G. Ingham, Dr. H. F. Munro, Dr. W. O. Gliddon, Dr. W. C. Winfrey, Dr. J. J. Danby, Dr. D. Samuel (since decd.), Major S. R. Gibbs, R. V. de A. Redwood, Col. C. R. White, Mrs. J. W. MacInnes, M.B. Serving Brothers : Dr. L. H. Wharton, Major S. Copley, Dr. C. H. Upham, Dr. P. C. Davie, Dr. A. E. A. Palmer, Dr. H. Riddell, Capt. R. H. Hadfield, Col. H. H. E. Russell, Dr. O. H. Hudson, Dr. A. J. Hopper, Dr. W. A. Jones, Dr. S. C. Bettencourt-Gomes, Dr. F. F. A. Ulrich, Dr. J. A. Carman, Dr. J. E. Brereton, Dr. H. B. Pierce.

British Social Hygiene Council

The seventh Imperial Social Hygiene Congress, under the ægis of various Government departments, will be held at the London School of Hygiene and Tropical Medicine on July 8th–12th. The Congress has been organised by the British Social Hygiene Council. Delegates, including many from overseas countries of the Empire, will be welcomed by the Earl of Plymouth, Sir Basil Blackett (president of the Congress), Sir Edward Grigg, and the High Commissioners of Australia, India, the Irish Free State, New Zealand and Southern Rhodesia.

Among matters to be discussed are: Domestic Relations and Matrimonial Cases; the Traffic in Women; the Juvenile Delinquent; Parents and Biology Teaching; Biology Teaching to Boys and Girls; Effects of Biology Teaching in the Colonies. A Conference on the Welfare of the Mercantile Marine will be held on the afternoon of Monday, July 8th.

Mental Hospitals Association

The seventeenth annual meeting of this association will be held at the Guildhall, London, on Wednesday next, July 10th, at 11 A.M.

Extensions at Mile End Hospital

A new out-patients' department and the balconies to the female ward block were opened last week at Mile End Hospital by Mr. Dan Frankel. The new balconies will take ten beds on each floor and have been fitted with the folding type of steel window.

Nottingham General Clinic

A fracture clinic is to be established at this hospital in order to control, unify, and continue the out-patient treatment of all fracture cases and follow its results. The sum of £36,750 has been received towards the £50,000 required for the erection of this wing.

Births, Marriages, and Deaths

BIRTHS

BRAYBROOKE.—On June 25th, at Tetbury, the wife of M. K. Braybrooke, M.R.C.S. Eng., of a son.

BUIST.—On June 27th, at Glasgow, the wife of Major T. P. Buist, M.B., Ch.B. St. And., R.A.M.C., of a daughter.

CHANDLER.—On June 26th, at Sunningdale, the wife of G. P. Chandler, M.D. Camb., of a daughter.

FOX.—On July 1st, at Hampstead, to Margaret and T. F. Fox—a son.

FRESHMAN.—On June 30th, at Welbeck-street, W., the wife of Edgar Freshman, F.R.C.S., of a daughter.

LEARMONT.—On June 19th, at Hovingham, York, the wife of Alan A. Learmont, M.B., Ch.B. Edin., of a son.

NEWBERY.—On June 21st, at Royal Naval Hospital, Haslar, the wife of Surgeon Lt.-Commdr. D. A. Newbery, R.N., of a daughter.

ORMEROD.—On June 21st, at Woodford Green, the wife of Thomas L. Ormerod, M.B., B.Ch. Oxon., of a daughter.

PILCHER.—On June 22nd, at Boston, Lincs, the wife of Richard Pilcher, F.R.C.S. Edin., of a daughter.

ROCHE.—On June 23rd, at Knaresborough-place, S.W., the wife of Alex. E. Roche, M.D. Camb., F.R.C.S. Eng., of a son.

ROSS.—On May 31st, at Ranikhet, India, the wife of Captain W. A. R. Ross, M.B., Ch.B. Edin., R.A.M.C., of a son.

SCHOLEFIELD.—On June 22nd, at Hereford, the wife of Bernard Scholefield, M.D. Oxon., F.R.C.S. Eng., of a daughter.

SEWELL.—On June 25th, at Sutton Scotney, Hants, the wife of Capt. E. M. Sewell, M.B., Ch.B. Edin., I.M.S., of a son.

MARRIAGES

CORCORAN—HAY.—On June 29th, at the Church of St. Joseph, Bedford, Capt. Thomas Martin Corcoran, M.R.C.S. Eng., R.A.M.C., to Elizabeth Maud, daughter of Col. W. N. Hay, C.I.E., D.S.O., and Mrs. Hay, of Bedford.

FARQUHARSON—HALLAM.—On June 21st, at St. Mary Abbots Church [illegible] A. Farquharson, M.B., C.M. Edin., [illegible] I., late of Darjeeling, to Agnes Mary, [illegible] late Mr. Henry Hallam, of Nottingham.

DEATHS

CLEMINSON.—On June 30th, at North Ferriby, Florence Stacey Cleminson, J.P., M.B., B.S.

GELLATLY.—On June 30th, at Cambridge, Jessie Handyside Gellatly, M.D., D.P.H. Edin., aged 52.

HEARDER.—On June 23rd, at Dinas Powis, Frederic Pollington Hearder, M.D. Edin., aged 62.

KITCHIN.—On June 28th, at Canford Cliffs, Bournemouth, Ernest Hugh Kitchin, M.B., B.Chir. Camb., aged 60.

MCALLUM.—On June 22nd, at Inglewood, New Zealand, Harold Guthrie McAllum, M.B., B.S. Durh., fifth son of the late Charles Octavius McAllum, of Newcastle-on-Tyne, aged 62.

MORTON.—On June 27th, at Lavender-gardens, S.W., Thomas Mahon Morton, L.R.C.P.I., L.R.C.S.I., aged 69.

RIDDELL.—On June 29th, at Beechwood, Bearsden, James Robertson Riddell, F.R.F.P.S. Glasg.

SCOTT.—On June 28th, at Charmouth, Dorset, Geoffery Easton Scott, B.M., B.Ch. Oxon., M.R.C.S. Eng., aged 26.

SMITH.—On June 28th, at Leatherhead, suddenly, Harry Edward Smith, M.B., B.Chir. Camb.

SUCKLING.—On the 30th ult., at "Beech Lawn," Edgbaston, Birmingham, Cornelius William, M.D., London, aged 80 years. Interred at Sutton Coldfield Cemetery, July 3rd.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Appointments

BROWN, W. PATERSON, M.B. Glasg., D.P.M., has been appointed Medical Director of the North Western Child Guidance Clinic, London.

DUFF, KEITH, F.R.C.S. Eng., M.C.O.G., Gynæcologist to the Dreadnought Hospital, Greenwich.

HILL, I. G. W., M.B., F.R.C.P. Edin., Clinical Tutor, Aberdeen Royal Infirmary.

LAMB, W. L., M.B., F.R.C.P. Edin., Clinical Tutor, Aberdeen Royal Infirmary.

MCNAIR, J. S., M.B. Glasg., Medical Superintendent of the Hospital for Tropical Diseases, London.

MORGAN, T. N., M.D. Aberd., Clinical Tutor, Aberdeen Royal Infirmary.

MORTON, H. S., M.B. Lond., F.R.C.S., First Assistant in the Gynæcological and Obstetric Department, London Hospital.

Certifying Surgeon under the Factory and Workshop Acts: Dr. J. D. Jones (Llanberis, Caernarvon).

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday; and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

SOCIETY FOR THE STUDY OF INEBRIETY.
TUESDAY, July 9th.—4 P.M. (11, Chandos-street, W.), Dr. William Brown: Psychology in Relation to Alcohol and Drug Addiction (Presidential Address). Dr. S. W. Patterson: Addiction to Endocrine Gland Extracts.

PADDINGTON MEDICAL SOCIETY.
TUESDAY, July 9th.—9 P.M. (at Great Western Royal Hotel, Paddington, W.), Dr. Alfred Welply: The Medical Practitioners' Union and the Trades Union Congress.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.
FRIDAY, July 12th.—5.15 P.M. (at West London Hospital), Annual General Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, July 8th, to SATURDAY.—PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N. All-day course in medicine, surgery, and the specialties.—ALL SAINTS' HOSPITAL, Austral-street, West-square, S.E. Afternoon and evening course in urology.—SOUTHEND GENERAL HOSPITAL, Southend. Week-end course in [illegible] (July 13th and 14th).— [illegible] only to members and

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, July 11th.—2 P.M., Dr. R. W. B. Ellis: Chronic Chest Disease. 3 P.M., Dr. D. Nabarro: Clinical Pathology in Pædiatric Practice (Demonstration).
Out-patient clinics: mornings, 10–12 noon. Ward visits: afternoons, 2–3.30 P.M. (except Wednesday).

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W.
WEDNESDAY, July 10th.—5 P.M. (1, Wimpole-street, W.), Dr. Paul Dudley White: Congestion without Myocardial Failure (St. Cyres Lecture).

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, Keppel-street, W.C.
TUESDAY, July 9th, and WEDNESDAY.—Conference for Medical Officers in Industry from the Tropics.

BRITISH ASSOCIATION OF RADIOLOGISTS.
SATURDAY, July 13th, and SUNDAY.—Congress in Birmingham.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION.
WEDNESDAY, July 10th.—4 P.M. (St. James' Hospital, Ouseley-road, Balham, S.W.), Dr. W. G. Barnard: Pathological Demonstration.

BRITISH SOCIAL HYGIENE COUNCIL.
MONDAY, July 8th, to FRIDAY.—Imperial Congress at London School of Hygiene and Tropical Medicine, Keppel-street, W.C.

UNIVERSITY OF BIRMINGHAM.
TUESDAY, July 29th.—3.30 P.M. (General Hospital), Mr. Cyril Raison: Abdominal Emergencies.

NOTES, COMMENTS, AND ABSTRACTS

LIFE AND LEISURE

THE ninth and final volume of the New Survey of London Life and Labour has now appeared.[1] The survey has occupied seven years, having been set on foot in 1928 on the initiative of the London School of Economics, with the assistance of grants from various bodies. The object was to follow the general scheme and methods of Charles Booth's inquiry, the results of which were published between 1889 and 1903, with such changes as are necessitated by alteration of circumstances and the development of new sources of knowledge. The endeavour has been to present a comprehensive record of social and economic conditions in London to-day, and a comparison with thirty or forty years ago.

The previous volumes have been principally concerned with the material conditions of the London worker's life and livelihood. The present volume deals with the pursuits of his leisure.

It is estimated that the average London worker's daily hours of labour when fully employed are now shorter than those prevailing 40 or 50 years ago by about an hour—rather more than an hour in the case of the unskilled labourer and rather less in that of the skilled artisan, and that the average worker in London has an increased margin of income above that which is absorbed by bare necessities.

The survey begins with a description of London popular amusements and entertainments, sports, hobbies, holidays, and outings—i.e., the full range of leisure pursuits which are primarily concerned with healthy enjoyment and recreation, rather than with self-improvement on the one hand or mere indulgence on the other. A distinction is drawn between cultural and non-cultural pursuits, and also between the active and passive types of amusement. It is found that the changes that have taken place in the amusements and recreation of the people have, generally speaking, affected the passive type of amusements much more profoundly than those of the active type. The progress of mechanisation of passive forms of entertainment, typified by the growth of the cinema and of broadcasting, is traced and an endeavour made to estimate their immediate and remote effects on the pursuits of leisure as a whole.

It is shown that in the main the cinema has created and supplied an entirely new demand, and that this is even more emphatically true of broadcasting. Forty years ago the part of working-class leisure now filled by the cinema was either non-existent or was to a large extent passed idly at the public-house, club, or street corner; and the change has been for the good even though the great educational possibilities of the films have so far been very imperfectly attained.

The second part of the survey deals with social organisations, the primary object of which is the better and more enjoyable use of leisure. The first chapter is concerned with workmen's clubs and there follow chapters dealing with social organisations for boys and girls. The critical importance of the period of adolescence, to the appreciation of which medical men are always trying to educate the public, appears clearly from the study of the various forms of social delinquency and evil habits which are surveyed in the third part of the volume. One of the main lessons of these inquiries into excessive drinking, gambling, sex-delinquency, and crime is that the root cause of these social maladies, in so far as they can be ascribed to environment is the absence or weakness of healthy interests.

The third part of the volume contains the results of careful investigations of some of the principal aspects of these social maladies. The survey of the drink problem is largely based on information obtained by visits to over 600 public-houses. The chapters on drink and gambling emphasise the concurrent decline of the former and the increase of the latter habit since the time of Charles Booth's survey.

One conclusion reached is that since drinking at the public-house is to a large extent an incident of social intercourse, "better accommodation and comfort tend to slow down the rate of drinking and therefore are to the public interest, though not perhaps to that of the brewers, whose object is rapid turnover, and who believe that this is favoured by 'perpendicular drinking'". The chapter on sex-delinquency includes a survey of the sources and predisposing causes, and also of methods of repression and prevention. The survey shows the change of character in sex-delinquency. Reason is given for the belief that at present there are not now more than 3,000 professional prostitutes plying their trade in the London areas, mainly in the regions near the main railway stations or docks where strangers and seafarers abound.

Since the war there has been an increase in the proportion of girls who indulge in "sex adventure" of a non-commercial nature, especially in the middle rather than in the working classes, but on the whole relationships between young people of different sexes are deemed healthier and more natural than they were twenty or thirty years ago. Among environmental conditions favourable to sex-delinquency the broken and undisciplined home is found to be the most important single factor.

For the chapter on crime a special analysis has been made by the courtesy of the commissioner of metropolitan police, of the dossiers of "first offenders" in 1927, so as to trace how far they have again been found guilty of offences during the subsequent five years. The broad result is to show that in the London area more than four-fifths of the male first offenders of 1927 were not again found guilty in the following five years. The age analysis discloses that it is the younger offenders who are most likely to be re-convicted. Of the minority who were again found guilty more than half re-appeared only once, but there was a small core of persistent offenders (about one per cent. of the total number of first offenders) who were re-convicted five times or more.

The fourth part of the volume consists of a set of original descriptions of the life of working-class families as seen from the inside, from the pens of the actual breadwinners or housewives.

The results of the survey will confirm the general impression of the direction of movement during the last half century. It provides ample scope for speculation on the whole question of leisure, its uses and abuses, which will clearly engross the attention of future generations.

The variety of organisations by means of which the Londoner may beguile his hours of freedom from work varies from the University Extension Courses to the gossip of the public-house; and follow him inexorably from the day-nursery into which his mother deposits him while she goes to work, to the men's institutes to which he can repair in his ripe years.

We cannot doubt that on the whole the movement has been to the good. But there is another side to the picture. It is suggested in this work that the decrease in drunkenness is of value to the community, not only for obvious reasons but also because drink is "undeniably an anodyne." Is it not equally true that for the person who must always be searching for amusement, who can never be alone, amusement surely represents merely a soporific and he is as much fleeing from reality as his grandfather did in the bar of a public-house?

Another unsatisfactory feature brought out is the enormous relative growth of "passive" amusements;

---

[1] The New Survey of London Life and Labour. Vol. IX. Life and Leisure. [illegible] Smith, G.C.B. London: P. G. [illegible] 445. 17s. 6d.

those which are presented ready prepared and predigested, requiring no intellectual or physical activity; the cinemas which, we are told, are capable of seating 1,000,000 per day, having sprung from nothing in the last 40 years; the greyhound racing courses, all started within the last fifteen years, and which now number 12 within the London area and whose total attendance in 1932 was ever 9,000,000.

The growth of passive amusements is out of all proportion to those which require active participation. Thus the cinemas seating capacity and the gate attendances quoted above may be contrasted with the increase in players of games on the grounds provided by the L.C.C.; (the figures given refer to the number of applicants to play respectively in 1926 and 1933), cricket 1078, against 1005, no increase; football 911, against 1006, less than 100 increase; or with the increase in the borrowers from public libraries in the County of London, which is estimated at 156 per 1,000. The increasing desire to take the easy mechanical path of collecting amusement or information, the latter especially from the B.B.C., in preference to the active cultivation of either hand or brain is certainly disturbing.

Finally, it is clear that there is an immense emphasis to-day upon "the herd." More and more do people do things together in crowds and there seems to be more in this than fortuitous circumstance; it is essentially a flight from the individual, from personal responsibility, and the need to think. It is true that the scout and guide movements and the working men's club and institute union, have seen the danger of this tendency and try to encourage individual activity and responsibility within the group. It is true also that there has been development in such individual hobbies as gardening, bird fancying, photography, and the like, yet the balance is strongly on the other side. The frequency of groups of hikers as compared with the solitary tramper, the masses of cyclists with their club badges, the vision of the pier at Brighton or the beach at Southend, all bear their noisy testimony to this fact. It is immensely desirable that people should have holidays and that they should escape from the dust and noise of London, but a very large percentage of the benefit is lost in the clamour of the crowds. It would seem that our amusements are tending to become as mechanical as our work, and though the craftsman has become irretrievably lost in the whir of the machine, surely it becomes the more important that his leisure hours should not be absorbed mainly or only in the merry-go-round of Hampstead Heath. Socialisation has helped much to improve the lot of the working man; nevertheless the world's best work has come from the solitary, and we need to see that we do not swamp all individual effort by our host of organisations.

INSTRUMENTS OLD AND NEW

SOME interesting additions have been made to the historical section and the collection of surgical instruments in the museum of the Royal College of Surgeons of England during the past twelve months, and among them are a number of Roman bronze instruments, found in London dating from the first century, which have been presented by Dr. Mervyn Gordon, F.R.S.

Some of the specimens, used for medical, toilet, and other purposes, were recovered from the bed of the Walbrook and others were found in the mud of the Thames, where they had lain since the Roman occupation. Six of the bronze toilet instruments, together with a bronze coin bearing the head of Vespasian A.D. 78, were excavated from the bed of the Walbrook in 1933, and twenty-three other instruments which include forceps, probes, spoons, and sounds, were found in the City. A further addition to the series include the blade of a forceps, bronze ear-scoops, sounds, and a large number of bodkins and needles of bronze, wood, and bone, which were found in the mud of the Thames. Among the toilet implements are two bronze nail-files and a combined nail-cutter and ear-scoop, evidently employed for manicuring purposes. From the same donor have also come several cutting knives of the mediæval period and a number of ointment jars, salve pots, and glass phials used by London apothecaries in the seventeenth and eighteenth centuries.

A large collection of surgical instruments used by the late Mr. Charles Heath, F.R.C.S., has been presented to the museum by his executors. His inventive genius is well illustrated in the many instruments he devised in connexion with his work on the nose, ear, and throat. They include examples of his dressing forceps with lifter handles, his tympanic knife, nasal polypus snare, laryngeal scissors, and mastoid gouges, and his mallets of standard silveroid. There are also a number of personal relics.

A gift of historical interest has been received from the trustees of the late Herbert Spencer. It consist of a rosewood box containing forty-eight microscope slides, mounted and prepared by Spencer between 1836 and 1840, which were originally kept at the Athenæum Club. The specimens are chiefly botanical, and consist of sections of leaves and stems of plants and trees such as the elder, dock, acacia, logwood, and turnip. Each slide is carefully labelled in his autograph with the botanical name of the specimen.

An exhibit showing the origin, development, and history of the tourniquet, arranged by Mr. C. J. S. Thompson, hon. curator of the museum, has now been completed and placed in the instrument room. The evolution of the appliance is shown from the primitive garrot used by Morell in 1674. This type was used in amputations in the seventeenth century and was described by Young of Plymouth in 1678 as "a hard linen wad to be placed over the vessel and held in place by a towel passed around the limb, its ends being tied together. The towel was then made tighter by a battoon or bedstaff." Petit's invention of the screw tourniquet in 1718, superseded the use of the cord and stick and limited the pressure to the artery. The advantage of the screw type was soon recognised, and from the eighteenth to the nineteenth century the appliance passed through many modifications. These are illustrated in the many examples of such instruments as Knaur's, Westphalen's axle-type, the English axle, the cylinder type, and the field tourniquet devised by Maclure. Other specimens include the tourniquets invented by Usher Pearson, Viedemann, and Perret, all of which form links in the history of the appliance.

All these additions to the museum will be on view between July 11th and 25th.

PRIMITIVE SOCIETIES

PROMISE of unusual interest for ethnological and anthropological students is made in a book with the inviting title of "Primitive Society and its Vital Statistics."[1] In the preface Dr. Krzywicki explains his concern to show that "there exists a division of primitive life not hitherto sufficiently taken into consideration by science—that of vital statistics" and, he contends, no study of primitive communities should be undertaken without their aid. A comprehensive table of contents summarises topics such as factors determining density of population among primitive communities; population estimates; causes leading to depopulation; effects of contact with higher cultures; natality and mortality experiences among various peoples, and so forth, while a really admirable bibliography calls for special mention.

Following these attractive preliminaries it is disappointing to find that though Dr. Krzywicki has assembled with infinitely laborious research a variety of data, these data are widely removed from modern conceptions of what is meant by the term "vital statistics." The material he examines with prodigious patience comprises an accumulation of facts and figures from the writings of a multitude of travellers and casual observers whose works have been published at various periods during the past two centuries. The author himself says that the numerical data are of very doubtful value, and that in some cases the figures cease to have any value whatsoever; yet he contends that as they are the only data available they must be referred to as the only existing evidence. Since the data so assembled and regarded as "evidence" are, in the main, conjectural estimates, we cannot agree that they constitute anything but unstable bases for scientific reasoning.

---

[1] Primitive Society and its Vital Statistics. By Ludwik Krzywicki, Ph.D., Professor of Social History in the University of Warsaw. London: Macmillan and Co., Ltd. 1934. Pp. 589. 20s.

It would be interesting to know what reasons persuaded Dr. Krzywicki to accept without question certain views and estimates, and to reject others. For example, on p. 93, when referring to the Report of the Commission appointed to inquire into the Decrease of the Native Population of Fiji, 1896, he expresses the opinion that "the findings contained in that Report are not perhaps always accurate as a whole," possibly because, in his view, they often "merely quote the explanations furnished by the natives themselves." In point of fact, the Fiji inquiry was an admirable piece of work, conducted on scientific lines, by thoroughly competent men fully conversant with the life and language of the Fijian peoples; such praise can but rarely be given to many of those whose works are liberally quoted in this book. It is difficult to understand how the author hopes to succeed in shedding new light upon important matters concerning primitive peoples, to trace the complex and imperceptible population changes at work among such peoples, or to discuss such problems as the fertility of women among hunting races and settled peoples, if his reasoning has to rest upon the shifting sands of unreliable or conjectural data which cannot, under any pretext, be defined as "vital statistics." Experienced workers among primitive peoples at the present day are convincingly certain that, in the absence of properly conducted inquiries by means of population enumerations *personally* organised and carried out at more or less regular intervals, together with personally collected data relating to births and other immigrants, to deaths and other emigrants, &c., it is impossible to measure the effects of various influences or particular customs on the life of a tribe or people. However pressing the desire, or ambitious the worker in this field of endeavour, the answer must still be that we shall not know the answers to problems peculiar to the lives of this or of that people without the help furnished by dependable statistical records.

TUBERCULOSIS RISKS FOR THE MEDICAL STUDENT

SINCE 1926 Dr. O. Scheel, of the communal hospital, Ullevaal, in Oslo, has kept its students under medical supervision (Nord. med. tidskr., March 30th, 1935, p. 481). His figures up to last summer concern 1176 students, and he classifies them in five groups: (*a*) 361 who were Pirquet-positive before beginning clinical work or during its first two months; (*b*) 207 who were Pirquet-negative before or during their clinical work; (*c*) 246 who were Pirquet-negative before or during their clinical work and were inoculated with B C G; (*d*) 262 who were Pirquet-positive when first examined after their clinical work had lasted at least two months; and (*e*) 100 who had a history of some manifestation of tuberculosis before they began their clinical work. (With only one exception these last were Pirquet-positive.) After the investigations had proceeded for some time, it was found desirable, when a Pirquet reaction was negative, to follow it up with a Mantoux intracutaneous injection of 0·1 or 1 mg. of tuberculin—to make sure. The proportion of positive reactions increased with the years of study more rapidly than among persons of the same age in other walks of life, but not so rapidly as among the Ullevaal nurses, more exposed to infection than the students. Tuberculous manifestations appeared nearly three times as commonly in the originally Pirquet-negative students as they did in the originally Pirquet-positive students. The students inoculated with B C G showed less than half the tuberculosis morbidity of the Pirquet-negative students who dispensed with B C G. The behaviour of the tuberculin reactions after the administration of B C G suggested that it is more potent when given by injection (214 cases) than when taken by the mouth (32 cases).

Scheel's studies throw new light on the question of super-infection of persons already Pirquet-positive. The tuberculosis morbidity among the originally Pirquet-negative students was comparatively high in the first two years of clinical work. There was no similar accumulation of cases among the originally Pirquet-positive students in their first two years. This implies that the importance of a super-infection is small. The figures in this study are too small to justify final conclusions, but they establish a good case for further research in this field.

HYGIENE FOR TEACHERS

A NEW edition of a work on hygiene and sanitation,[1] apparently intended for those training to be school teachers, has reached us. It is, on the whole, accurate in its facts, of which perhaps too many are included for this class of student. It is doubtful whether it is worth while introducing topics like anaphylaxis, allergy, and Ehrlich's side-chain theory when their implications cannot be fully explained. An extensive bibliography, supplied for collateral reading, consists almost entirely of works published in the U.S.A., and is therefore not readily available for the British student.

DEAD AND LIVING ANATOMY

A LITTLE book[2] written for students and practitioners of chiropody will be doubtless of value to them in their efforts to reach a higher level from which they can survey their field. Remembering the author's preface, we take no account of omissions, and but little of errors in detail, which possibly are irrelevant to the special reader's work. The parts are more fully dealt with as one approaches the foot, but it is here that we look in vain for applied anatomy. The values of the arches and the primary value of muscles here might have been stressed; the incidence of the line of weight transference, and the effect on it and on the arches of different positions of the foot, and so on, might have been dealt with, even diagrammatically. The figures are clear and good if we disregard minor errors, and we hope that the author will include some consideration of living anatomy in another edition.

THE RETREAT, YORK

THE annual report of this registered hospital for the treatment of mental disorders, which appeared recently, is the 138th in succession, a fact which speaks for the long repute of the institution. At the beginning of the year 1934, the period covered by the report, there were 182 patients; 95 were admitted during the year, the total number under care being 277; of these patients 71 were discharged and 20 died, 186 being therefore on the books at the beginning of 1935. Of the admissions, 54 per cent. were voluntary patients, and of the 71 discharges 23 were classified as recovered and 37 relieved, the remainder not having improved. All the 20 deaths were from natural causes. Dr. Neil Macleod, the medical superintendent, writes in the report of the significance of out-patient departments in relation to the mental hospital, stating that every town of some size and importance should be equipped with a functional nervous disorder clinic where neurotic conditions can be properly studied and appropriate methods of treatment evolved. Such a clinic, he says, exists in York, and the numbers of those attending it is increasing, but, nevertheless, he feels that a much larger number of patients in the neighbourhood require and desire psychotherapeutic help. He looks to such clinics in all parts of the country to help the general public to realise that "mental illness is not a doom or a blight, but is a form of disfunction which demands enlightened treatment, whether in an out-patient department or in a mental hospital, according to the degree and quality of the malady."

Vacancies

For further information refer to the advertisement columns

Barrow-in-Furness County Borough.—M.O.H. &c. £900.

Belfast, Royal Maternity Hospital.—Res. M.O. At rate of £52.

Birmingham, General Hospital.—Res. Anæsthetist. £70.

Birmingham, Little Bromwich Hospital for Infectious Diseases.—Jun. Asst. M.O. £300.

Bolingbroke Hospital, Wandsworth Common, S.W.—H.P. At rate of £120.

Bolton, Royal Infirmary.—H.S. £125.

Bristol Royal Infirmary.—Sen. Cas. H.S. Also Sen. Obstet. H.S. Each at rate of £100. H.P.'s and H.S.'s to Spec. Depts. Each at rate of £80. Also H.S. to Ear, Nose, and Throat Dept. £80.

British Postgraduate Medical School, Shepherd's Bush.—Anæsthetist. Also 1st Asst. in Dept of Medicine. Each £300. Also 2 H.S.'s.

Buckinghamshire County Council.—Asst. County M.O.H. £500.

Buxton, Devonshire Royal Hospital.—H.P. also Asst. H.P. At rate of £200 and £150 respectively.

Cancer Hospital, Fulham-road, S.W.—Surgeon.

Canterbury, Kent and Canterbury Hospital.—2 H.S.'s. Each at rate of £125.

Cape Town Hospital Board.—Medical Asst. to Radiological Dept. £600.

Cardiff, Prince of Wales' Orthopædic Hospital.—Sen. and Jun. H.S. At rate of £200 and £100 respectively.

Cardiff, University College of South Wales and Monmouthshire.—Asst. Lecturer in Dept. of Physiology. £400.

Ceylon, Colombo Municipal Council.—City Microbiologist. Rs. 12,000/- a year.

Chester, Royal Infirmary.—H.P. also H.S. Each £150.

Chichester, Royal We [illegible] and Jun. H.S.'s. At rate of £175.

Children's Hospital, [illegible] Asst. Surgeon.

Chorley, Lancs, Chor [illegible]—H.S. At rate of £150.

Cobham, Surrey, Schiff Home of Recovery.—Res. Surg. O. At rate of £200.

Colchester, Essex County Hospital.—H.P. £150. Also Asst. H.S. £120.

Croydon, Mental Hospital, Upper Warlingham, Surrey.—Asst. M.O. £350.

Derbyshire Hospital for Sick Children.—Res. H.S. At rate of £130.

Devon, Royal Devon & Exeter Hospital.—H.S. At rate of £150.

Devonport, Prince of Wales's Hospital.—H.P and Cas. O. At rate of £100.

Doncaster Royal Infirmary.—H.S. to Eye and Ear, Nose, and Throat Depts., Cas. H.S. Also H.S. Each £175.

Eastbourne, Princess Alice Hospital.—Res. H.S. £150.

Evelina Hospital for Sick Children, Southwark, S.E.—H.S. At rate of £120.

Gloucestershire, Royal Infirmary.—2 H.S.'s, also H.P. Each at rate of £150.

Great Yarmouth, General Hospital.—H.S. £140.

Grimsby County Borough.—Asst. M.O.H., &c. £500.

Grimsby and District Hospital.—Sen. and Jun. H.S.'s. £200 and £150 respectively.

Hackney Hospital, High-street, E.—H.P. At rate of £120.

Halifax County Borough.—Asst. Maternity and Child Welfare M.O. £500.

Hampstead General and N.W. London Hospital, Haverstock Hill, N.W.—H.P. also Cas. Surg. O. At rate of £100.

Harrogate Royal Bath Hospital.—Res. M.O. £156.

Herefordshire General Hospital.—Res. Surg. O. £150.

Hospital for Consumption and Dis. of Chest, Brompton, S.W.—Res. M.O. £350.

Hospital for Sick Children, Great Ormond Street, W.C.—Med. Reg. £300.

Hospital for Tropical Diseases, Gordon-street, W.C.—Surgeon.

Huddersfield Royal Infirmary.—H.S. At rate of £150.

Hull Royal Infirmary.—H.S. to Ophth. Ear, Nose and Throat Depts. Second H.P. and third H.S. Each at rate of £150. Also H.P. for Sutton Branch Hospital. At rate of £160.

Ilford [illegible] O.H. £500.

Ilfor [illegible] *ital.*—Asst. Surg. to Fracture and [illegible]

Ipsw [illegible]—H.P. £150.

Ipsw [illegible] *Ipswich Hospital.*—H.P. and H.S. [illegible]

Kingston and District Hospital.—Asst. Visiting Obstetrician. £300.

Lancaster Roy [illegible] At rate of £130.

Leicester City [illegible] M.O. £900.

Lincoln, Coun [illegible] t rate of £150.

Liverpool, Hal [illegible] *treet.*—Res. M.O. At rate of £120.

Liverpool, Royal Children's Hospital.—Hon. Asst. Phy.

Liverpool, Stanley Hospital.—H.P. and 3 H.S.'s. Each at rate of £100.

London Homœopathic Hospital, Gt. Ormond Street, W.C.—Hon. Phys. for Dis. of Nervous System.

Macclesfield, General Infirmary.—2nd H.S. At rate of £150.

Manchester, Ancoats Hospital.—H.S. At rate of £100. Also [illegible] te of £100.

[illegible] *'tal and Holt Radium Institute,* [illegible] . O. At rate of £150.

[illegible] *for Infectious Diseases.*—Jun. Res. Asst. M.O. At rate of £250.

Manchester, Victoria Memorial Jewish Hospital, Cheetham.—Clin. Pathologist. £250.

Middlesbrough, North Riding Infirmary.—Cas. O. Also third H.S. At rate of £150 and £125 respectively.

Middlesex, North Middlesex County Hospital.—Surgeon. £500. Asst. M.O. At rate of £350. Also Jun. M.O.'s for Special Hospitals. Each at rate of £250.

Mitcham, Wilson Hospital.—Res. M.O. At rate of £120.

Montrose, Royal Asylum.—Jun. Asst. M.O. £300.

Newcastle General Hospital.—Two H.S.'s and one H.P. Each at rate of £150.

Newcastle-upon-Tyne Hospital for Sick Children.—H.P. and H.S. Each at rate of £100.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Res. Anæs. At rate of £100.

Nottingham, Children's Hospital.—Res. H.S. At rate of £150.

Nottingham General Hospital.—H.S. for Fracture and Orthopædic Depts. £300.

Nottinghamshire, C. C. Education Committee.—Asst. School M.O. £500.

Oldham, Boundary Park Municipal Hospital.—Res. Asst. M.O. At rate of £200.

Paddington Hospital, Harrow-road, W.—Asst. M.O. £250.

Plymouth, Prince of Wales's Hospital, Greenbank Road.—Asst. H.S. At rate of £120.

Preston and County of Lancaster, Royal Infirmary.—H.S. for Special Depts. At rate of £150.

Princess Elizabeth of York Hospital for Children, Shadwell, E.—H.S. Also Cas. O. Each at rate of £125.

Princess Louise Kensington Hospital for Children, St. Quintin-avenue, W.—Hon. Asst. Phys.

Radium Beam Therapy Research, Radium Institute, 16 Riding House Street, W.—Asst. M.O. At rate of £250

Reading, Royal Berkshire Hospital.—Surg. Reg.

Rhondda U.D.C.—2 Asst. M.O.'s. Each £500.

Royal Air Force Commissions.

Royal Eye Hospital, St. George's Circus, S.E.—Hon. Asst. Surgeon.

Royal National Orthopædic Hospital, Great Portland-street, W.—H.S. for Country Branch. At rate of £150.

Royal Naval Medical Service.—Nine M.O.'s.

Royal Northern Hospital, Holloway, N.—H.P. At rate of £70.

Ryde, Royal Isle of Wight County Hospital.—Res. H.S. £180.

St. Andrew's Hospital, Devons-road, Bow, E.—H.P. At rate of £120.

St. Bartholomew's Hospital Medical College.—Helen Cave Memorial Scholarship. £200.

St. Helens C.B.—Two Asst. M.O.H's. £500 and £600 respectively.

St. Luke's Hospital, Sydney-street, Chelsea, S.W.—H.P. At rate of £120.

St. Thomas's Hospital.—M.O. in charge of Physio-Therapeutic Dept.

Salford Royal Hospital.—Orthopædic Registrar. £100.

Scotland, General Board of Control.—Deputy Commissioners. Each £953.

Sheffield, Children's Hospital.—H.S. At rate of £100.

Sheffield, Royal Infirmary.—Ophth. H.S. At rate of £120. Also H.S. and H.P. Each at rate of £80.

Southend-on-Sea, General Hospital.—Obstet. Officer. £125.

Stafford, Standon Hall Orthopædic Hospital.—H.S. £200.

Sudan Medical Service.—M.O. £E720.

Sunderland, Royal [illegible]

Swansea, General [illegible] At rate of £150.

Victoria Hospital [illegible] *Chelsea, S.W.*—H.P. and H.S. Each at rate of £100.

Warrington County Mental Hospital, Winwick.—Asst. M.O. £500.

West End Hospital for Nervous Diseases, Gloucester Gate, N.W.—Res. H.P. At rate of £125.

West End Hospital for Nervous Diseases, 73 Welbeck Street, W.—Hon. Med. Psychologists for Child Guidance Unit. Also 2 Hon. Clin. Psychologists.

Westminster Hospital, Broad Sanctuary, S.W.—Wander Scholarship. £250.

Wigan, Royal Albert Edward Infirmary and Dispensary.—H.S. At rate of £150.

Willesden General Hospital, Harlesden-road, N.W.—Hon. Surgeon.

Wolverhampton, Royal Hospital.—H.S. for Fracture and Orthopædic Dept. At rate of £100.

Woodside Hospital, Muswell Hill, N.—Res. H.P. At rate of £100.

Woolwich and District War Memorial Hospital, Shooters Hill, S.E.—Res. M.O. £175.

Worcester, Royal Infirmary.—Jun. H.S. £120.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Newport, Isle of Wight.

PRINCESS BEATRICE HOSPITAL, LONDON.—Lord Lord Carisbrooke is appealing for £100,000 for this hospital at Earls Court, which was called after his mother when it was rebuilt in 1930. It is now £68,000 in debt and costs £24,000 a year to maintain, about £9,000 of this being contributed by patients. The hospital's financial troubles have been caused by the coming of the economic crisis at a time when building was in progress, this making it impossible to complete the original schemes.

ADDRESSES AND ORIGINAL ARTICLES

A CLINICAL STUDY OF HEADACHES *

By Sir Edmund Spriggs, K.C.V.O., M.D., F.R.C.P. Lond.
SENIOR PHYSICIAN, RUTHIN CASTLE

(Concluded from p. 8)

Migraine

That migraine is different from other headaches has probably always been recognised, though the word has been used at times to include habitual headaches generally. With a reservation about the word "diurnal" which calls to the mind the prevalence in those days of malaria, Galen's works provide a description as modern as any.

> "Cephalæa is a diurnal headache with vehement occasions from small causes. The sufferer cannot endure noise, raising of the voice, the brilliance of light, or movement; but seeks quiet and a dark chamber on account of the severity of the pain. Some are as under the blows of a hammer, some as if crushed and distended; and in not a few there is pain to the roots of the eyes. There are, as in epilepsy, remissions when there is complete freedom."

One of the sufferers in this series, a man, used words which were almost the same—"as if hit with a hammer."

Migraine is the most frequent of headaches. In this series it forms the largest group, numbering 103 cases; to these may be added 14 migrainous subjects placed in other groups because the migraine factor seemed of lesser importance. Thus there were 117 migrainous persons among 500 patients with considerable headaches, or 23 per cent. Taking the whole period under review, and remembering the minor headaches which were omitted from this series, migraine was not present in more than 2·5–3 per cent. of the 4796 patients. This figure is lower than that given by some authors.

The characteristic features of migraine may be put under nine headings:—

1. It is periodic, using the word to mean not simply intermittent, but in the stricter astronomical sense of the (more or less) regular return of the same or similar phenomena.
2. It often begins in childhood or youth.
3. It is often hereditary. Then, in order, are:—
4. Premonitory symptoms, sometimes half a day or a day before.
5. The aura.
6. One or both-sided headache, which may be intense.
7. Nausea, vomiting, polyuria.
8. Exhaustion after severe attacks.
9. Complete recovery.

There is no part of the typical sequence which may not be absent. The aura, the headache, the misery, the nausea, the vomiting may each occur in the migrainous subject with none, some, or all of the others. And should the sufferer be subject to other aches or pains the migraine will seem to take them into its periodic course.

Fig. 3 shows the age at onset for the whole group and for the two sexes. In this series the latest age of onset was 62, in a woman. The oldest person admitted with migraine was a man of 66. He had had it on and off all his life. and was the subject of cervical arthritis. Four others were over 60. The well-known tendency of migraine to cease with advancing years can be illustrated by a gradation of these patients. The attacks may cease at any age without any special treatment, but are apt to recur with strain or ill-health, as many of the histories show. Treatment for the exciting cause or factor may again lead to relief.

EXCITING CAUSES

Any disturbance or strain may precipitate a migraine in a person who is at that time liable to it. The exciting causes are, therefore, as numerous and variable as are the circumstances of our daily lives. Fifty different causes, or in different wordings, were mentioned by these 103 persons.

Nervous causes, when put together, formed much the most frequent, 39 cases. They may be grouped as follows: upset, agitation, or anxiety, 15; excitement (including dinner or bridge party, talking, visitors), 14; working mentally too much or too long, 10.

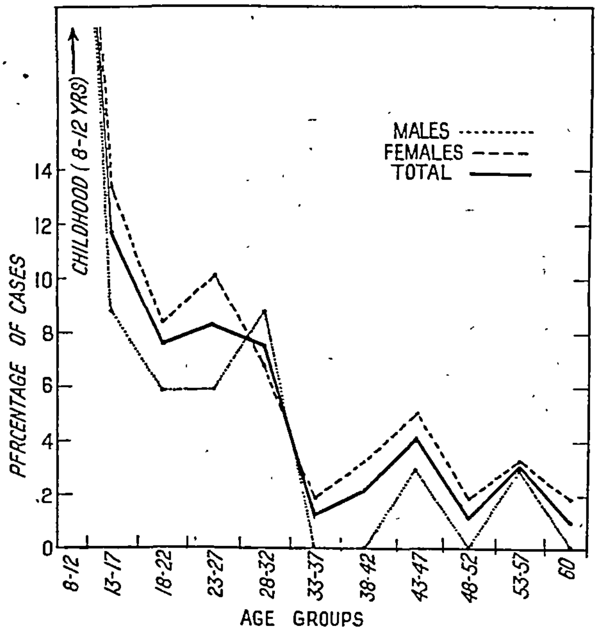

FIG. 3.—Age at onset of migraine. The incidence in the age-group 8–12 (not shown in chart) is 53·2 per cent. made up of males 67·6, females 45·0.

Simple fatigue or getting tired—i.e., not specially mental fatigue—was mentioned by 17. In one even a walk would bring on a headache.

The next large group is that of food, some of the instances being typically allergic or atopic. There were 18 out of the 103 who recognised that the wrong food would bring on a headache.

The main causes they gave were rich food, creamy things, alcohol, port; and the following foods were each mentioned once: pork, ham, beef, eggs, nuts, roughage. Tobacco was given as a cause once. The skin tests, and a careful trial, are valuable in the diagnosis of allergic and atopic exciting causes. It appears, however, from these numbers that care should be taken in unduly restricting diet by guesswork. Some of these patients had for a long time gone without certain foods in vain because some other person had been helped by that deprivation.

Other causes reported were: constipation, 9; indigestion or abdominal pain (various conditions), 7; motoring, 5; "journeys," 4; riding, 2; menstruation (before or after), 5. East winds and cold weather were mentioned by 4, exertion in hot weather by 1. In 5 headaches were brought on by reading at night, any glare or strong light, or the cinema.

---

* The Croonian lectures for 1935, delivered before the Royal College of Physicians of London on May 14th, 16th, and 21st. The lectures were illustrated by numerous case-histories and lantern slides.

Sleep is as a rule the best cure of all for a migraine. It appears, however, sometimes as an adverse influence, for two or three were liable to headache if they slept too long in the morning. One young man had a regular morning headache, which was avoided when he was waked at 7 o'clock and took a walk before breakfast. Those who get a headache on a Sunday, of whom there were two in this series, one a doctor, probably belong to this group. One mentioned that a heavy sleep at night would bring on a headache and two an afternoon sleep.

The following exciting causes were mentioned by one person each—a particular place, a stuffy room, boredom, a dog barking.

In childhood the bilious attack or headache is liable to come on with the excitement of anticipation such as before an examination or a party. With advancing age anticipation is better borne and the headache will come on after the party. And with the further progress of years the nervous system can bear both the thought and the event without disturbance.

AURÆ

The best known prodromal sign, and the commonest in this series, is a feeling of unusual fitness. George Eliot wrote "I am dangerously well to-day." Other prodromal symptoms were tiredness, restlessness, poor sleep, depression, a distaste for food, indigestion, or "an undesirable sensation that I am in for it."

Just half the patients reported an aura, and the proportion was the same in each group. The auræ were mostly visual, one only was coloured, "a rainbow." Non-visual auræ were, in order of frequency, hot or sore eyes, dizziness, pressure or tension on one side, aphasia, soreness of scalp, pins and needles in arms and legs, stiffness, numbness, abdominal discomfort.

It has been suggested that the absence of an aura in many migrainous patients is due to the fact that migraine often comes on in the early morning and that the aura is over in sleep, or wakes the person and is forgotten. Whilst such a view cannot be disproved, the figures in this series lend it no particular support. In the first place 18 patients whose headaches came on in the daytime described no aura. They include some who have been subject to characteristic and severe migraine for many years, are good observers, and have had headaches coming on at all times of day without auræ. Secondly, of 33 patients whose headaches came on "on waking" or "in the early morning" 15 had auræ, 18 had not.

The symptoms of the mid-headache were then related in the order of frequency in the whole series, with details of illustrative cases. Most of the attacks were severe. In five there were mental symptoms at the height of the headache and two became maniacal for the time being, until controlled by morphia.

SITE

The site of the headache was often unilateral to begin with, passing in some cases over to the other side or becoming diffuse. In some it might start on either side, and the patient knew whether the attack would be severe or not according to which side was first painful. The ache was in most cases in the fore part of the head, the various main sites being mentioned in the following order: frontal, 25; eyes, 24; temporal, 24; diffuse, 13; vertical, 10; occipital or neck, 14; parietal, 3.

Of the 14 cases with migraine whose pain was in the occipital region 3 had a local cause in a complicating cervical arthritis and fibrositis. It is notable also that of the remaining patients whose migrainous headache was felt in the occiput or neck all had some gastric or duodenal affection—ulcer, gastritis, or delay, or of the colon—spasm with diverticulosis, disorder after partial colectomy, colitis.

AGE

It is common in medical writing, and migraine has received as much study and attention as any disease, to write of migraine as classical or idiopathic if arising in early life, and to apply some other term such as acquired or symptomatic migraine to that arising later. My experience suggests that, apart from the one feature of age at onset, the more thoroughly the case is inquired into the less clear the distinction becomes. It is recognised by all that true idiopathic migraine, excited by a variety of adverse influences, is more likely to be so excited at times of special strain. The onset of migraine in adolescence, for example, is ascribed to the strain of puberty, and afterwards that of entering on the serious business of life. But a greater strain may come later in the conduct of that business or from ill-health and may give rise to migraine then. Further, in some of the cases dating back to childhood a definite physical lesion was present, the treatment of which relieved and cured the headache. And, if too much stress be laid upon the distinction between idiopathic and symptomatic migraine, there is a danger lest the idiopathic cases may be regarded as definitely diagnosed and that further steps be not taken.

The following are examples of migraine arising in early life, recurring with new physical strains, and improving again with suitable treatment.

In a young woman of 27 migraine began with puberty at 14, at first about weekly, then at the periods. She had a nervous but sensible temperament. The headaches became worse with, in turn, appendicitis, duodenal ulcer, a love reverse, and extraction of teeth, improving as each was dealt with or endured. She is now happily married and headaches are few and less severe; but she finds it necessary to keep to a régime of regular rests and a plain anti-constipation diet.

A professional man suffered from migraine with aura till he was 50. He was then "fairly free" until, after a chill, he developed fibrositis at the age of 60. Typical migraine then returned. With treatment he improved greatly and now reports a year later that both headache and rheumatism are well.

The following is an example of migraine arising in later years.

An able man of 53, with no family history of headache, developed migraine on active service at the age of 41. He was a barrister, and his complaint on admission was that after feeling particularly fit and "following the exaltation that one gets in court" he would see flashes with partial blindness, succeeded in 20 minutes by a frontal headache on both sides. With the ache came photophobia, vertigo, discomfort in the abdomen, and constipation. He would persist with his work in court, but, if circumstances allowed, and especially the vomiting, which continued for hours, could sleep. Aspirin gave some relief. After the headache he was "done up." He was subject to constipation and some teeth were infected at the roots.

With treatment the headaches ceased for the time and he was better for some months, ascribed by him to "the nerve-steadying influence of the place." But attacks recurred in court. He therefore took a legal appointment involving important and responsible work, but out of court, and writes that though at times he gets "a migrainous condition, when I feel that the fumes of my distemper are about me " yet the former severe attacks are avoided by this adjustment of life.

It has been stated that acquired migraine is more resistant to treatment. As regards the results of treatment while under immediate care these figures support that statement. But when later results are looked at there is a better proportion of good results in the group of migraine arising after 40.

In the two groups of 30 cases of migraine arising after 20 years of age and 11 after 40, the headaches were in all respects typical of migraine, except that they dated back in many a few years only. They were associated with a definite morbid state, physical or nervous, and were lessened or abolished by removal of the associated lesion or strain. It appears that at all ages up to the fifties, or even over, typical migraine may develop, following very various strains.

My opinion is that there is no real difference in severe cases such as are described here, between "true" and "acquired" migraine, and I venture to suggest that for clinical purposes the distinction should be abandoned.

PERSISTENT AND INTENSE HEADACHES

Most headaches are intermittent. Persistent, that is continuous, headaches were complained of in 45 only of the 500, that is, in 9 per cent. They were found, in order of frequency, in the following groups: organic intracranial, vascular, nephritic, psychasthenic, and mental.

Intense headaches, in which the headache is the only complaint or filled the field to the exclusion of other symptoms, occurred in 85 cases, 17 per cent. of the whole. They were distributed as follows: migraine 36, hyperpiesis 8, nephritis 6, sinusitis 6, eyes 5, rheumatic, nervous exhaustion 4 each, constipation 3, and smaller numbers in other groups.

Mechanism of Headache

To the mechanism of headache I shall refer only in so far as certain features of the cases under review seemed to bear upon that much discussed problem. Recent observations, both experimental and upon the human brain in long operations, during which the patient is under little or no anæsthetic for a good part of the time, show that the most sensitive areas are close to the vessels in the pia mater. This conforms to D. Waterston's work on the extreme sensitiveness of the outer coverings of arteries and their neighbourhood. The dura mater is less sensitive, and the radiations and grey matter not sensitive to ordinary stimuli. For a long time a vasomotor control of cerebral arteries was not demonstrated, but the work of Huber and the more recent confirmation of Penfield showed that nerves and nerve-endings are present along the vessels; also the experimental results of Forbes, Wolff, and Cobb that the pial vessels contract and dilate with stimulation of the sympathetic and vagus respectively.

The vascular theory of headaches, and especially of migraine, foreshadowed for at least two centuries, and well stated by E. Bramwell, was that a preliminary spasm of arteries, associated with the aura, was followed by dilatation at the stage of the pain, which is compared to that of hotache. The peripheral nerves involved are the intracranial branches of the fifth; and it is stated that no headache occurs on that side if the Gasserian ganglion is removed.

That a headache can be produced by vascular changes is probably accepted by all, and is supported by the interesting observations of G. W. Pickering and W. Hess upon the brief headaches following intravenous injection of histamine. The lecturer and his colleagues used subcutaneous injections of histamine frequently in giving fractional test-meals, and S. W. Patterson and J. H. Anderson had made notes of 50 consecutive cases of such injections; 44 of the 50 were not subject to headaches. In 12 of them headaches occurred after histamine, five of which were severe and of longer duration than those described by Pickering and Hess. In 6 of the 50 who were subject to headaches, 4 had a headache after histamine. In 2 the headache produced had the same features as the headache to which the patient was liable. This might mean that the mechanism of the histamine headaches was the same as that of the patients' own headaches, or simply that the injection of histamine acted as an exciting cause.

The vascular theory as at present stated does not seem to account fully for the duration of headaches, e.g., in some of these cases for 12, 24, or 48 hours. The explanation suggested, on that theory, is that as a result of ischæmia from spasm, followed by dilatation, œdema occurs around the vessels, with an increase of intracranial pressure which keeps up the pain and the vomiting. We do see painful spasm of arteries in other parts of the body and it is controlled by nerves, as shown by the benefit, in suitable cases, of sympathectomy. But those arteries are generally diseased. Do we see ischæmia with resulting œdema? Yes; but it cannot be repeated often without damage to the area concerned. It may be said that perhaps the capillary bed in the brain is so extensive that a better recovery can take place than in a peripheral area in a limb. But if so an ischæmic œdema would also occur less easily. Now the headache of migraine can, unlike the attacks of epilepsy, recur again and again throughout a long life without any evidence of cerebral damage. The subjects of migraine seldom become insane, and the headaches of the psychotic groups in this series were not migrainous. It is true that cerebral thrombosis has been reported as a sequel of severe migraine, and there were at least three in this series who developed that condition. But cerebral thrombosis is not uncommon in elderly people, and the clinical features of the patients concerned did not satisfy the lecturer that the thrombosis was a result of the headache.

The long duration of certain headaches might be more easily explained by a consideration of the work of Dale and of Lewis upon the production of histamine and its effects, together with the theory of allergy. It is conceivable that in a sensitised area, owing to the combination of an antigen and cellular antibodies, with effusion through the capillary wall, the damaged endothelial cells might go on giving out histamine, with resulting further reaction, for a long time. The allergic reactions we are able to see—for example, urticaria—can pass away leaving no damage.

Although, as above mentioned, the grey matter is not sensitive to ordinary stimuli, yet the conception cannot be put aside that the tissue which perceives pain may do so independently of its sensitive coverings. If so a true functional headache may have its seat in the sensorium. But it must be admitted that errors of perception of other sensations than that of pain are, apart from insanity, uncommon.

MIGRAINE AND THE PITUITARY FOSSA

It has been observed (Timme) that in certain cases of migraine, especially those occurring severely with menstruation, the pituitary fossa is less roomy than normal; and it is suggested that the headache is a result of the swelling of the pituitary body in a contracted space, which occurs at those times in association with ovarian activity. A. P. Thomson has published an interesting paper on these cases, describing several in which improvement followed the use of a suitable ovarian extract.

My colleague, O. A. Marxer, points out that a lateral view, taken alone, may be deceptive, and to establish that the pituitary fossa is really constricted antero-posterior as well as lateral radiograms must be taken.

Mr. Marxer has examined the pituitary fossa in 656 out of 3000 consecutive cases: 539 persons were not subject to headache; among these were 16 shallow or bridged fossæ (in 4 men and 12 women) = 3 per cent.: 117 persons were subject to headaches; among those were 4 shallow or bridged fossæ (all in women) = 3·4 per cent. In 35 of the 117 persons the headaches were migrainous: 2 of the shallow or bridged fossæ were in this group = 6 per cent. Both were in women; in neither was the headache especially menstrual.

In this series, therefore, the proportion of cases with a constricted pituitary fossa, though definite, was small, and was not much greater in the persons with headache than in those without them.

Treatment

The first aim of treatment is to abolish or influence what the lecturer had called the second order of causes—namely, any condition or disease, physical or mental, which tends to depress the health. The treatment, therefore, medical and surgical, varies with each group of patients according to the diagnosis made, indeed with each patient. Many examples were given in reviewing the various groups.

No habitual headache, whether life-long or arising in adult life, should be accepted as a necessity to be simply palliated and endured, until every possible source, not only of physical but also of mental and psychical disorder, has been excluded so far as possible by an investigation and by appropriate treatment.

In habitual headaches, and especially in migraine, where no removable cause can be found, the establishment of a regular régime of rests, exercise, food, and, when possible, peace of mind, is of first importance. The Galenical writings say the sufferer "must have sleep, happiness, and quiet, and avoid noise, strife, and wine bibbing." In those past the full energy of midlife, a valuable lesson to learn is that an hour's rest, alone, on a couch, or, better, a bed, with sleep if possible, sometime in the middle of the day, will increase the power to work and lessen strains. The itch to be doing something all the time is a fosterer of headaches. Many patients in reply to inquiry write as did an intellectual overactive man, who used the words: "the greatest help has been in learning how to live."

In women the menopause comes to the aid of many, but not always if other strains go on. An artificial menopause has been successful in some, a disappointment in others.

Measures found of special value between attacks in this series include, besides the regulation of rests, work and exercise: reduction of tobacco, of coffee, and the avoiding of skin-sensitive foods and sometimes of other foods. Of drugs gardenal or luminal is valuable. Many find gr. $\frac{1}{2}$ twice a day, especially at times of stress, a useful preventive. Calx sulphurata, an ancient remedy, has been very helpful in some. One grain, twice a day to begin with, is reduced when the subject becomes odorous of sulphides. The drug should be continued for several months; later gr. 1 once or twice a week may be enough. In others of this series calcium lactate, grs. 5–10 t.d.s. seemed to be followed by benefit. Strychnine, arsenic, sodium glycocholate, pituitary, thyroid, ovarian preparations, eucortone, insulin, peptones, calcic protein injections, a combination of iron, copper, and vitamin D, desensitisations—all are recorded as having been followed by good in suitable cases.

TREATMENT OF THE ATTACK

In almost all several methods of treatment have been used. In migraine alone 35 different combinations of physical and medicinal measures are noted as having been successful in different people in arresting or relieving the attack. The following summary was prepared by marking down each time that any given measure was noted, at the end of the period of treatment, as having been useful.

Physical means (in order of frequency of mention, as above).—Rest, sleep, dark, quiet, warmth, induction of vomiting, an enema, gastric lavage, liver pack, pressure on eye, temple, scalp. Capsicum, mustard leaf, thermogene to head and nape, poultices to abdomen, sneezing,

Food or drink (in order).—None, glucose and fluid, tea, glucose, fluid and orange juice, copious hot water, a meal (in a mild case).

Drugs (in order).—Bromides, gardenal, luminal (must be early). *Cachet* of aspirin, phenacetin āā grs. 2, pyramidon and caffeine āā gr. 1. Phenacetin. Acetanilide. A cachet of sulphate of quinine, pyramidon, phenacetin, and magnesia. Belladonna. Novalgin, allonal, dial, and similar drugs. Calomel, sulphate of magnesia, aperients.

Heroin and morphia are unsuitable drugs for habitual headaches. There are, however, a few, a very few, cases in which the physician should use them. As Freud wrote: "No remedy is proof against misuse; if a knife will not cut neither will it serve a surgeon." Ephedrine is a useful remedy in many. Adrenaline is recommended by T. C. Hunt, given very gradually under the skin—e.g., ♏ 1 a minute up to ♏ 10–15. We can confirm his report that headache may be arrested thereby. But some are upset by the cardiovascular effects and prefer other methods.

Among the combinations of measures recorded as having been successful are: In mild attacks the well-known procedure of complete rest at once, with a drug of the phenacetin group or aspirin before vomiting threatens. Or one of the above-mentioned cachets, sometimes a double one, and much tea. Three examples may be given of the combinations which led to arrest of severe headaches.

1. Rest, dark, an immediate enema, calomel gr. 1/10 hourly, 2 drachms of 50 per cent. sulphate of magnesia, and a pint of hot water an hour later.

2. Rest, sipping of hot water, a cachet, and an enema of glucose saline.

3. Rest, dark, no food or drink, phenacetin, and a mustard leaf to the nape.

In a case of the type of clavus hystericus, in which the patient became maniacal, gr. $\frac{1}{3}$ of morphia was given two hourly until asleep; and in the meantime an enema of glucose saline, barley sugar, and insulin.

Dehydration of the brain, by magnesium sulphate in the bowel, or more thoroughly, by putting concentrated saline into the blood, is perhaps worth a trial in severe cases.

[No direct surgical measure for the relief of headache was used in this series. The lecturer spoke of the experience of others from opening the dura mater and cutting nerves, of tying the meningeal artery, and of sympathectomy. He suggested that, on the experimental evidence, a simple trephine hole might be tried in some cases of intense and frequent headache.]

Results

In habitual headaches, and especially migraine, any large reduction in the number and severity of the attacks is a good result.

The following figures are compiled from the records of my colleagues contained in the reports to the family doctor at the end of the stay of each patient.

Immediate result of treatment of 327 patients from three weeks to two months or more.

		Per cent.
No (or slight) headache	216	= 66·1
Much improvement	93	= 28·4
No improvement	11	= 3·4
Worse	7	= 2·1

The test, in the case of those in whom no one causative factor can be eliminated, comes when the patient resumes ordinary life. The returns from the inquiry as to present state, for which thanks are due to a large number of professional brethren, are still arriving. Up to the present the figures are:—

Present state known in 268; 213 are alive; 55 are dead.

In 179 of the 213 alive definite reports upon the symptom of headache have been furnished.

		Per cent.
Report no (or slight) headache	72	= 40·2
Much improved	67	= 37·4
The same	30	= 16·8
Worse	10	= 5·6

In reviewing ancient and modern methods of treatment, some valuable weapons have of late been added to our armoury. None is suitable for all cases and there are no miracles. The way to treat headaches is to find out what is wrong and try to put it right. My feeling after this inquiry calls to mind the old story, which used to be in the German grammar book, of an aged man who called his sons to his bedside and said: "There is treasure in the vineyard. Dig." And they came closer, asking: "Where shall we dig?" But, his breath failing, their father whispered "Dig," and passed away. They dug here, and there, then the parts between, and at length the whole vineyard. And they found no gold. But the next year the yield of grapes was threefold.

WATFORD PEACE MEMORIAL HOSPITAL.—The accommodation and equipment of this institution are being taxed to the utmost, and it is hoped to erect a three-storey building which will provide room for 52 ordinary patients and 19 private patients. No estimate of the cost of the new buildings has yet been given, but it is said that considerably more than the £35,000 which is in hand will be required. A nurses' home is also urgently wanted. The average cost of in-patients for last year was £2 18s., and the contributory scheme collected £9608.

FURTHER EXPERIENCES OF SERUM IN THE TREATMENT OF PNEUMONIA

BY DUNCAN LEYS, D.M. Oxon., M.R.C.P. Lond.
PHYSICIAN TO SELLY OAK HOSPITAL, BIRMINGHAM

IN September, 1933, a detailed report[1] was published on the use of concentrated antipneumococcus serum in a small series of cases of Type I. lobar pneumonia at Selly Oak Hospital. During the period Oct. 1st, 1933, to April 30th, 1935, the sputum of almost every case admitted to the hospital with the diagnosis of pneumonia has been examined for the purpose of typing the pneumococcus, and 101 cases of Type I. pneumonia, together with 20 cases of Type II. pneumonia, have been treated with intravenous serum. In all, 367 adult patients were "typed," but 53 of these proved subsequently not to have pneumonia, and it is significant that in all but one of the 53 the pneumococcus in the sputum belonged to Group IV. (i.e., did not agglutinate with serum Types I., II., or III.). The ultimate diagnoses in these cases included pulmonary tuberculosis, pulmonary embolus, asthma, bronchitis, infective endocarditis, coronary thrombosis, pyæmia, and pyelitis.

Seven cases of typical primary pneumonia which showed no pneumococci in the sputum, in spite of repeated examination, are excluded from the analysis, and 11 cases in which meningitis was diagnosed within twenty-four hours of admission to hospital are separately described. The latter have been included, however, in the analysis of types, since pneumonia was present in all of them.

GENERAL OBSERVATIONS

The type-incidence and gross mortality of the remaining 307 cases, 79 (26 per cent.) of which were females, are shown in Table I. A clinical or post-mortem diagnosis of broncho-pneumonia as distinct from lobar pneumonia was made in 24 cases, analysed in Table II., where it will be seen that 20 belonged

Rec. = recovered; S. = serum given; ns. = no serum given.

Table III. sets out the sex-incidence and mortality of all the 307 cases analysed; a more detailed study of Type I. and Type II. cases will be found below.

From a city of over a million inhabitants, Selly Oak Hospital receives roughly a third of all cases of pneumonia sent to hospital, drawn from all parts of the city; conclusions drawn from the study of cases in the hospital are therefore some guide to conditions throughout the city area. The seasonal fluctuation is approximately the same for all types, March and April showing the highest incidence, August and September the lowest, but epidemics of one type or another, lasting over two or three weeks, are often observed.

Children.—It has frequently been stated, on the basis of examination of throat swabs during acute pulmonary infection, that Types, I., II., and III. are relatively uncommon in childhood. Since the pneumococcus can be cultured from the throats of most healthy persons, such a conclusion was speculative, and the results of typing the pneumococci found in pleural fluids, cerebro-spinal fluid, and sputum, give quite a different picture. Fairbrother[2] has recently shown an incidence of 87 per cent. Type I. pneumococcus in empyema occurring in school-children, in a series of 59, and a series of 25 children under the age of fourteen at Selly Oak Hospital during the period under review has given a type-incidence which corresponds very closely with that found in adults, i.e.:—

	I.	II.	III.	IV.
Cases	11	5	2	7
Per cent. ..	44	20	8	28

Meningitis.—Recovery from pneumococcal meningitis without serum has been reported[3] after cisternal drainage, and there have been a few reported recoveries of Type I. cases after the use of concentrated serum intrathecally. None of the cases treated at Selly Oak Hospital during this period has recovered, but results in at least one case (to be reported separately) have been sufficiently striking to make it an obvious duty always to attempt treatment when the type proves to be I. or II. Of 11 cases of pneumococcal meningitis diagnosed within twenty-four hours of arrival, one Group IV. case followed trauma, one Type II. case was otitic, and the remaining 9 were due to Type I. pneumococcus. In 7 of the latter serum treatment was attempted, the routes used being intravenous, intrathecal, and intracisternal; the largest dose given to any one patient was 420,000 units, over a period of one week.

Empyema (diagnosed in life or post mortem) developed in 26 cases out of 307, an incidence of 7 per cent. Table III. shows the type-incidence and organism cultured from the pus: where this was the pneumococcus it was always of the same type as that occurring in the sputum. It is noteworthy that streptococci were found in the pus in 5 out of 7 cases of Group IV. pneumonia, as compared with only one among 12 Type I. cases, and 2 among 7 Type II. cases.

Taking this information together with the figures for those cases of Group IV. infection which proved to be either broncho-pneumonia or not pneumonia at all, it seems legitimate to deduce either (*a*) that if it were practicable to differentiate all Group IV. pneumococci into their true types, fatal cases associated with Group IV. pneumococci would correspond with one of the rarer virulent types, or (*b*) that all Group IV. pneumococci are relatively avirulent, and that some other organism, possibly the streptococcus, is causative in the fatal cases in which Group IV. pneumococci are found. I am not, however, in agreement with some writers who contend that it is possible to make a clinical diagnosis of type, since many characteristic cases of lobar pneumonia occurred in the Group IV. series.

Typing.—The direct method of typing is of great value in expediting treatment: if sputum is immediately available, a result can be obtained and treatment begun in less than an hour. Discrepancies between results of direct typing and of typing by mouse passage occur, but are rare, and the correction necessary is almost always to convert a directly typed Group IV. (i.e., no capsule swelling observed) into one of Types I., II., or III. The wet direct method,[4] using methyl-violet as a stain, is always used at Selly Oak, and rabbit serum appears to give rather more rapid and obvious capsule swelling than horse serum. Direct results are very easily obtained from cerebro-spinal fluid and pus.

Type III. Pneumonia.—While a rather higher proportion than for other types occurred in old age, Type III. pneumonia was found at all ages, and the gross mortality was slightly less than for Type II. cases. A relatively small elevation of temperature was characteristic, and some cases, particularly in old age, were apyrexial; but no other clinical peculiarity was observed in Type III. cases, and apyrexial cases were seen in infections by Types I. and II. and by Group IV. No cases of empyema or meningitis occurred among the 23 patients with Type III. pneumonia.

SERUM TREATMENT

Type I. serum.†—Excluding the 7 cases of meningitis, 94 cases of Type I. pneumonia were treated with intravenous concentrated serum. There were 20 deaths in this group, giving a 21 per cent. mortality for treated cases. During the same period there were

---

* If cases of broncho-pneumonia are excluded, the total number analysed becomes 283, with a type incidence:—

I.	II.	III.	IV.
130 (46%)	58 (20%)	20 (7%)	75 (26%)

† The serum employed was prepared by the Lister Institute of Preventive Medicine, and supplied by Messrs. Allen and Hanburys Ltd. It contained 10,000 international units in about 3·5 c.cm.

admitted to the hospital a further 30 patients with Type I. pneumonia who were not treated with serum.

The reasons why these patients did not receive serum were various: (*a*) crisis shortly after admission, and a clinical judgment that serum was superfluous (not always, unfortunately, justified by the event); (*b*) the patients being under twenty and the prognosis therefore being good: I am now personally of the opinion that it is not justifiable to withhold serum on account of age; (*c*) delay in typing, or absence of sputum; (*d*) the temporary charge of wards by acting physicians who were not in agreement as to the value of the treatment.

Two of these patients had meningitis on arrival, and if these are excluded, there were 9 deaths, with a mortality of 32 per cent.

Of 28 patients given serum before the end of the third day from the onset of symptoms, 3 died (12 per cent. mortality); in one of the fatal cases a severe untreated hypochromic anæmia had been present for some months, and in another the pneumonia was a complication in chronic nephritis. Of 20 cases treated on the fourth day, 5 died (25 per cent. mortality), including one delayed death due to erysipelas originating in an empyema wound, and one death from pneumonia in a patient with recent rheumatic carditis. Of 15 cases treated on the fifth day, 3 died (20 per cent. mortality). Of 21 cases treated on the sixth day or later, 5 died (24 per cent. mortality). No complicating conditions of importance were present in the fatal cases in the fifth and sixth day groups. A few cases have been excluded from this analysis on the grounds of uncertainty as to the day of onset of symptoms.

The results of treatment begun during the first three days of illness are thus twice as good as the results of treatment delayed to later days. This experience is in accordance with the published data of larger series in the United States, and is comparable with the results obtained in the treatment of, for example, diphtheria by antitoxin; but it must be remembered that, other things being equal, a definitely worse prognosis must always be given when a case of pneumonia is removed to hospital after the first few days of the disease, because of the shock of removal at that critical period. The number of Type I. cases received at Selly Oak (since typing was first performed as a routine) and receiving no serum, has been too small to allow me to supply comparable figures.

The average dose of serum was, in the cases which recovered, 57,000 units, and in the fatal cases 90,000. The smallest total dose employed was 20,000, and the largest 260,000, in a case which ultimately proved fatal.

Type II. cases.‡—The number of cases treated with serum is proportionately smaller than for the Type I. cases, and too small for use as statistical evidence. Twenty cases received serum, with 6 deaths (30 per cent.); in the same period, 37 cases were admitted and received no serum (one case of meningitis is excluded), with 11 deaths (30 per cent.). Nine patients received serum before the end of the third day from onset of symptoms, of whom 2 died (22 per cent.); 9 received serum after the end of the third day, and 4 of them died (44 per cent.). The average dose of serum given in cases which recovered was 63,000 units; and to fatal cases, 75,000. The minimum total dose given was 20,000 and maximum 140,000, to a patient who recovered.

Clinical impressions of the effects of serum.—In 1933 I referred to the frequency of untoward reactions after the intravenous injection of Type I. serum (tachycardia, rigors, hyperthermia). Using a different batch of serum, such reactions have subsequently been entirely absent, and that some factor in the serum itself was primarily responsible is conclusively shown by the fact that reactions were not seen when trials were made with the original batch after reconcentration by a different method, at the Serum Department of the Lister Institute. Not all patients, however, gave reactions with the original batch, so that conditions obtaining in the patient's tissues must be held to be of some importance; reasons were given in the first paper for supposing that the reactions were not "allergic," and that therefore methods designed to "desensitise" were of no avail. No precautions to ascertain the degree of sensitivity to horse-serum were employed in the present series. Three patients treated with Type I. serum showed a mild urticaria 8–12 days after receiving serum.

Unpleasant reactions with Type II. serum, however, have been frequent, and of the same nature as those previously described for Type I., except that hyperthermia was not observed. The question arises as to what extent unpleasant and possibly dangerous reactions are connected with efficacy in therapeusis. While it is true that an immediate crisis was observed, following such reactions, in many cases in the first series, and in Type II. cases in the present series, equally spectacular results have been often seen in Type I. cases in the present series which showed no symptoms of "shock" or rigors. Subjective sensations of improvement after the first dose of either serum were usual.

I still consider that the blood culture gives the best guide both to prognosis and to the need for serum treatment. Repeated blood cultures, however, in a few of the fatal cases of both Type I. and Type II. pneumonia receiving serum, did not show pneumococci, and the reason for the failure to respond to serum in these cases is not clear. It is my opinion, and that of my colleagues also, that the clinical rules for prognosis in pneumonia are very far from being infallible, and that the blood culture, in spite of these occasional discrepancies, is a more certain guide. Abscess-formation, whether in pleura, lung, pericardium, or elsewhere, appears to mark the end of the usefulness of intravenous administration of serum, and was present in those fatal cases treated with serum but not showing septicæmia, in which post-mortem examination was allowed. Several instances of sterilisation of the blood (some only temporary) following serum treatment, were observed.

An attempt was made, following the reports of Francis,[5] to make use of intradermal reactions to capsular substance as a guide to serum dosage; the process was found to be too time-consuming for routine use, and in the few patients tested, the reactions were not sufficiently clear to afford useful information.

CONCLUSIONS

The extended use of concentrated serum in the treatment of pneumonia at Selly Oak Hospital has confirmed the earlier impressions of its value. I consider that there is a strong probability that the use of larger doses of Type II. serum, which the fear of severe reactions at present makes difficult, would produce as good results as those obtained with Type I. serum. The need for very early treatment is obvious.

A METHOD OF MEASURING THE AIRWAY OF THE NOSE

By Sir Leonard Hill, M.B. Lond., LL.D., F.R.S.
DIRECTOR OF RESEARCH, ST. JOHN CLINIC AND INSTITUTE OF PHYSICAL MEDICINE, LONDON

Into one nostril a nipple-shaped tube is inserted so as to fit the nasal opening in airtight fashion. A glass tube, with a rubber nipple fixed on its end, answers the purpose; the orifice cut in the end of the nipple should be about 5 mm. in diameter. This tube is connected with a water manometer, the other end of the tube of the manometer is connected to a tambour set to write on a drum.

To provide a simple instrument for clinical use the drum is dispensed with, and the excursion of the meniscus—that is of the column of water in the manometer—is noted as each breath takes place through the other nostril, the mouth being kept shut.

A record of the manometric excursion produced by breathing is taken first from one nostril and then from the other. When the breathing is through a partially obstructed nostril the excursion will be greater because of the greater pull of the expanding lungs on the nostril in which the recording tube is inserted. Now the excursion of breathing through the normal nostril can be made equal to that through the partially obstructed side, by narrowing the external opening of the former. This can be effected by inserting into it a very short length of nipple-shaped tube. A number of such tubes are used, each having a different sized opening. The openings experimented with increased as follows:—

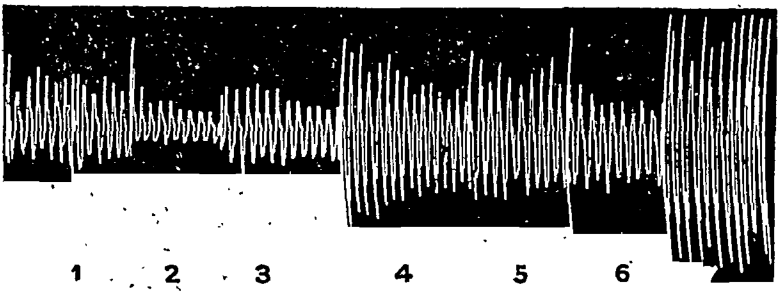

FIG. 1.—Subject T

1. Right side of nose.
2. Ditto with 28·5 sq. mm. tube, respiration easier.
3. Ditto with 19 ,, ,, ,, ,, ,,
4. Ditto with 14 ,, ,, ,, ,, increased.
5. Left side of nose.
6. Ditto with 19 sq. mm., respiration easier.
7. Ditto with 14 ,, ,, tube, respiration much increased.

The right side of the nose has naturally the freer air-passage.

Diameter.	Surface area (approximate).
2. 6 mm.	5½ sq. mm.
3. 5 ,,	9½ ,, ,,
4. 2 ,,	14 ,, ,,
4. 9 ,,	19 ,, ,,
6. 0 ,,	28½ ,, ,,
11. 0 ,,	95½ ,, ,,

In place of these tubes one tube can be used to which a slit is attached, which can be varied in width by means of a screw, a gauge being provided to indicate the size of the slit.

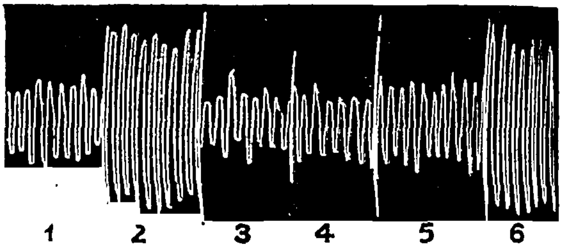

FIG. 2.—Subject L

1. Right side of nose.
2. Left side of nose (naturally partially obstructed).
3. Right side of nose with 28·5 sq. mm. tube.
4. Ditto with 19 ,, ,,
5. Ditto with 14 ,, ,,
6. Ditto with 9·5 ,, ,,

It must be borne in mind that when the recording tube is inserted into the more obstructed side of the nose the wing of the nostril is pushed out. This relieves the obstruction if this be at the ostium internum, and makes the taking of the record possible. Supposing it is found after insertion into the normal nostril of the tube, with 9½ sq. mm. opening, that the excursion of the breathing through that side becomes equal to the excursion through the partially obstructed side, then the conclusion is reached that the area of the breathing passage on the partially obstructed side is no larger than 9½ sq. mm. (*Figs.* 1 *and* 2).

We have seen that in the case of a nostril partially obstructed at the ostium internum the insertion of a tube by pushing out the wing relieves the obstruction (Figs. 1, 5, 6). The insertion of a tube can therefore be found, the orifice of which causes a breathing excursion equal to that when there is no tube in this nostril.

Next, in the case of either nostril of a subject, the tube can be found which just causes an increase of excursion obtained during quiet respiration when the subject is sitting at rest.

The size of opening sufficient for normal quiet respiration in most subjects is found to be about 14 sq. mm. When the tube of 19 sq. mm. or larger opening is inserted it makes the breathing easier by pushing out the wing (Figs. 1 and 2). A larger opening than 19 sq. mm. is required when the subject does exercise—e.g., stepping on to a box 6 inches high twelve times a minute. By increasing the exercise

3. Right side of nose obstructed with 14 sq. mm. tube.
4. With heater on (increased excursion).

the normal nostril was found to have an opening of about 30 sq. mm.—the size of the end of a pencil.

After inhalation of a solution containing adrenaline the relief of the partially obstructed side of the nose was such that the excursion is made almost equal to that on the normal side. The method thus shows the effect of treatment. (Compare Figs. 1 and 2 with Fig. 6.)

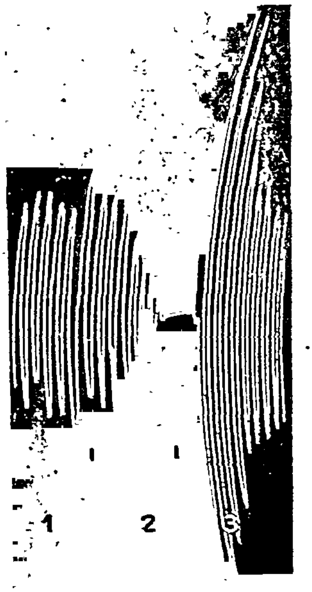

FIG. 4

1. Left side of nose (naturally partially obstructed).
2. With heater on air-way totally obstructed.
3. Respiration following turning off of heater.

An opening as small as 5½ sq. mm. may suffice, at any rate for a short time, for an adequate supply of air to the normal subject when at rest, but the excursion becomes greatly increased, the inspiration and expiration being prolonged at the height of each. In some the respiration is made less, and in others more, frequent as the result of such partial obstruction.

The irradiation of the skin with a small source of dull red heat (an electric coil 4 in. by 2) increases the partial obstruction (Figs. 3 and 4), and in about 50 per cent. of subjects the switching on of a bright source, such as a small tungsten arc, held some two feet away, or an incandescent lamp, relieves the obstruction (Fig. 5). After adrenaline inhalation the heater has no effect (Fig. 6). The method lends itself very well to the demonstration of these phenomena and to the refutation of the assertion made by Dufton and Bedford,[1] and

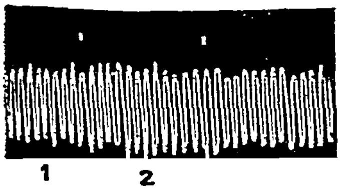

FIG. 6

1. Left side of nose after adrenaline inhalation.
2. Turning heater on had no effect.

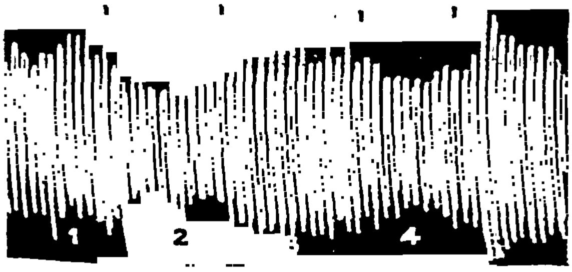

FIG. 5

1 and 3. Left side of nose (naturally partially obstructed).
2 and 4. Respiration made easier by turning tungsten arc on to the skin.

of Winslow and others,[2] that "nose opening" rays[3] do not exist. Dishoek [4] has confirmed such ray action.

In the case of one asthmatic subject it was found that a tube opening of 28½ sq. mm. produced an increase of breathing excursion, while one of 14 sq. mm. may be required to effect this in normal people. In the case of two other asthmatics one side of the nose was found to have an obstruction equal to a tube with an opening of about 5½ sq. mm. It is obvious that the effect of any operative procedure for relieving such obstruction can be measured by the method.

This research was carried out with the aid of a grant for expenses from the Medical Research Council.

APLASTIC ANÆMIA

TWO FATAL CASES TREATED BY BLOOD TRANSFUSION AND PENTOSE NUCLEOTIDE

By J. McDonald Holmes, M.B. Leeds,
M.R.C.P. Lond.

HONORARY PHYSICIAN, STAFFORDSHIRE GENERAL INFIRMARY;
LATE ASSISTANT MEDICAL OFFICER, ST. STEPHEN'S
HOSPITAL (L.C.C.), LONDON

These two cases are reported in view of the present interest in pentose nucleotide therapy in granulocytopenia or "agranulocytosis." In aplastic anæmia, as is well known, granulocytopenia may form part of the blood picture, in addition to diminution of red cells and platelets. In the cases here recorded an attempt was made to influence this granulocytopenia by pentose nucleotide therapy, while maintaining the red cell count at a reasonable level by blood transfusion. The attempt failed and both patients died without any real improvement having taken place.

Mills [1] divides aplastic anæmia into primary or idiopathic, and secondary groups. Primary aplastic anæmia he regards as very rare. The secondary group contains those cases which follow the administration of various toxic substances such as benzene and arsenobenzene derivatives. Excessive exposure to radiation from radium or X rays may also give rise to an aplastic anæmia. The prognosis is extremely poor in all varieties which attain any degree of severity, and although many remedies have been suggested and tried, blood transfusion seems to be the only one which has produced any benefit, and this is usually no more than temporary.

McCarthy and Wilson [2] have reported 34 cases of aplastic anæmia, 17 of which were treated by blood transfusion alone, and of these only 3 recovered—a mortality of 83 per cent. They advocated the use of pentose nucleotide as a supplement to blood transfusion, but gave no records of cases in which it was tried. Their observations referred particularly to aplastic anæmia following the administration of arsenobenzene (arsphenamine) derivatives. The first case described below was one of this kind; in the second no causal factor was discovered.

THE TWO CASES

Case 1.—A single woman, aged 30, was admitted to St. Stephen's Hospital on Sept. 22nd, 1933, with a primary labial sore which had been present for three weeks. The blood Wassermann and Kahn reactions were strongly positive. There was a slight sore-throat and headache on admission, but no rash or obvious secondary lesion. There was nothing of note in the previous history of the patient. Apart from the syphilitic primary lesion she was perfectly well. No splenic enlargement could be detected and no abnormality was found in the cardiovascular, respiratory, or nervous systems. Antisyphilitic treatment was begun, and in all nine injections of N.A.B. (neoarsphenamine) were given at weekly intervals, the first two doses being 0·45 g. and the rest 0·6 g. Nine injections of bismuth in the form of 1 c.cm. of Chlorostab were also given during the same period. These injections ended on Nov. 29th., 1933.

The subsequent course was as follows. Dec. 5th: patient developed severe bilateral quinsy, with cervical adenitis and high pyrexia; swab taken revealed streptococci, but no Klebs-Löffler or Vincent's organisms. 7th: quinsy on left side incised; other treatment consisted of hot fomentations and hydrogen peroxide and saline gargles; pyrexia still continued. 9th: some improvement in throat condition, but pyrexia was still high and patient looked severely ill and anæmic. Dec. 12th: throat improving and adenitis subsiding. 18th: blood count showed severe anæmia of normocytic type with marked granulopenia; throat still further improved but pyrexia continued. 19th: began a course of pentose nucleotide in daily doses of 1·4 g. intramuscularly; blood culture negative. Dec. 23rd: no improvement in blood picture; blood transfusion of one pint from a group II. donor; pyrexia continued; pentose nucleotide reduced to 0·7 g. daily. 27th: temperature slightly lower, and patient felt a little better, but no improvement in blood picture had occurred; slight bleeding per vaginam; pentose nucleotide stopped. 30th: blood transfusion one pint. 31st: blood transfusion one pint; patient no better and pyrexia still continued around 103° F.; no great improvement in blood picture. Jan. 1st: 1934, much worse, in a semi-comatose state. Jan 2nd: died at 1 A.M.

The blood counts are summarised in Table I.

* Reticulocytes less than 1%.

This patient received eleven injections of pentnucleotide (Smith, Kline, and French) of 0·7 g. each. For the first four days two injections per day were given, and on the remaining days this was reduced to one injection of 0·7 g.

Post-mortem Findings.—External appearances: Large subcutaneous bullæ had rapidly developed overnight, and contained hæmorrhagic serous fluid; the whole body was grossly distended by gas formation. Pharynx: some œdema and ulceration of fauces. Trachea and bronchi: mildly inflamed, contained much frothy muco-pus. Pleuræ: numerous hæmorrhagic petechiæ; each cavity contained about a pint of serous exudate. Lungs: grossly œdematous. Heart muscle: very pale and flabby. Aorta: slight fatty streaking. Liver: very pale and fatty, and honeycombed by gas. Spleen: very pale and soft but not enlarged. Stomach and intestines: nothing of note. Kidneys: very pale with much cloudy swelling. Adrenals: marked diminution of cortical lipoid. Brain: very œdematous and affected by post-mortem gas-formation.

The right femur and a rib on section revealed marked pallor and fatty infiltration of marrow. On microscopical examination the bone-marrow was seen to be almost completely aplastic, with very few leucocytes and no erythroblastic tissue. There was nothing else of note beyond toxic visceral changes. Culture of the fluid from the subcutaneous bullæ gave no growth.

CASE 2.—A Jewish girl, aged 22, was admitted to hospital on March 9th, 1934, with a history of bleeding from the gums during the previous six weeks. This bleeding had been only occasional and never severe. There had also been bruising of the skin on slight trauma during the same period. The patient felt very exhausted and had been in bed for ten days before admission. Copious vaginal hæmorrhage was the reason for her being sent to hospital. There was nothing of note in her previous history and the menses had previously been normal.

She was very pale and obviously anæmic. There was copious bleeding from the gum margins and per vaginam, and numerous ecchymoses and petechial hæmorrhages over the trunk and limbs. There was no ulceration of the mouth or pharynx, and the liver and spleen were not palpable. A generalised soft systolic murmur was audible over the precordium. Blood pressure 102/80. Examination of other systems revealed nothing of note.

The course of the events was as follows. March 9th: high pyrexia; treated by hot vaginal douches and adrenaline swabs to gums; 10 c.cm. of hæmoplastin injected. 10th: blood count; bleeding checked to some extent by local treatment. 12th: blood picture much worse; a small transfusion of six ounces was given; the gums stopped bleeding after this but the vaginal bleeding continued, though less in amount; patient still bruised very easily; pentnucleotide 1·4 g. given intramuscularly. 13th: still bleeding slightly per vaginam; blood transfusion of one pint; pentnucleotide increased to 2·8 g. daily; still high continuous pyrexia 102°–103°. 14th: blood picture considerably improved as far as red cells were concerned; bleeding entirely ceased; blood transfusion of one pint, which was followed by a slight angioneurotic œdema of the face. 15th: red cell count still further improved, but no improvement in white cell count; no further bleeding or ecchymoses. 16th: still no improvement in white cell count. 17th: commenced bleeding again from gums and vagina; blood transfusion one pint. 19th: general condition much worse; no remission of pyrexia, which ran between 103°–104°; some respiratory distress and slight signs of consolidation at pulmonary bases. 21st: patient comatose, bleeding from mouth again; died in evening.

Pentnucleotide was continued up to the day of death; and in all 21 g. were given. The blood counts are summarised in Table II.

* Platelets 20,000 c.mm.

Post-mortem examination revealed severe toxic visceral changes, basal pulmonary œdema and broncho-pneumonia. The liver showed conspicuous fatty degeneration. There was pallor and fatty infiltration of the marrow in the shaft of the right femur and a rib, and histologically these showed almost complete aplasia apart from a few very scattered leucocytes.

COMMENT

The two cases showed no qualitative alteration in the red cells other than a slight anisocytosis, as is usual in aplastic anæmia. Granulocytopenia was prominent in both of them, and pentose nucleotide therapy was tried in the hope of stimulating the granulopoietic activity of the bone-marrow, but not the slightest response was obtained.

Evidence is increasing that dramatic success can be expected of pentose nucleotide therapy only in those cases of granulocytopenia attributable to a "maturation arrest" of the granulocytes of the bone-marrow.[3] In such cases much hyperplasia of the granulopoietic elements of the marrow is found, and this is in contrast to the hypoplasia or aplasia seen in aplastic anæmia. There is usually no associated anæmia, or only a very slight diminution in red cells.

If this supposition be correct the failure of pentose nucleotide in the above two cases was to be expected, for in both of them there was almost complete aplasia of the marrow. Failures in the treatment of granulocytopenia by pentose nucleotide have been recorded by Fairley and Scott,[4] Blackie,[5] Hall,[6] and Fettes and Whitby,[7] and it is probable that many of these cases were of the aplastic variety, not associated with hyperplastic changes in the marrow. In the two cases reported here the presence of severe anæmia in addition to the granulocytopenia made it necessary to give blood transfusions. It may be said that transfusion was too infrequent; but as often happens, the transfused blood was quickly destroyed and gave little benefit apart from a slight improvement in the red cell count of the second patient.

A larger number of cases is obviously necessary before any definite conclusions can be reached with regard to the use of pentose nucleotide in aplastic conditions of the bone-marrow; but in view of the uncertain ætiology of many of these conditions it seems to be worth a trial.

My thanks are due to Dr. T. W. Griffiths and Dr. G. Goodhart for their kind coöperation.

APLASTIC ANÆMIA FOLLOWING NEOKHARSIVAN

By Alex. H. Imrie, M.B. Glasg., M.R.C.P. Lond.
ASSISTANT PHYSICIAN TO OUT-PATIENTS, ROYAL INFIRMARY, GLASGOW

Among the untoward results of the treatment of syphilis by the organic arsenical preparations aplastic anæmia and the other blood dyscrasias seem to have received very little attention in this country. Nevertheless, although rare, they are well recognised, especially in America, where McCarthy and Wilson[1] in 1932 published an analysis of all the available recorded cases and added 2 from their own observation. Bickford and Tilghman[2] in 1933 recorded 2 non-fatal cases of purpura hæmorrhagica occurring during the treatment of congenital syphilis with neoarsphenamine, and Scarf[3] (1934) a case of aplastic anæmia with recovery also following neoarsphenamine. These conditions are rare and McCarthy and Wilson were able to collect only 79 cases in all. Cole and his co-workers[4] (1931) observed only 2 cases in a total of 338 complications arising in the treatment of 1212 patients over a ten-year period, Phelps[5] had 2 cases in 272,354 injections, and Combes[6] 1 in 4000 patients.

CLASSIFICATION AND CLINICAL FEATURES

The classification of these conditions of the blood has always presented difficulties, for they all appear to be due to greater or less depression of the bone-marrow, but it seems that this depression may affect the various formative functions in varying degree and the provisional classification suggested by Kennedy[7] is likely to prove as useful as any. The importance of being able to classify a case is that the prognosis and treatment vary in the different types.

The suggested groups are: (1) thrombocytopenic, (2) granulocytopenic and agranulocytic, and (3) aplastic. A few cases are atypical and defy exact classification. Of the 79 cases referred to above, 65 fell into one or other of the three groups in the following proportions:—

—	I. Thrombocytopenic.	I. (sub-group). Thrombocytopenic and granulocytopenic.	II. Granulocytopenic and agranulocytic.	III. Aplastic.
Cases ..	12	7	12	34
Died ..	0	1	4	28

(Seven cases were placed in Sub-group I. because they showed granulocytopenia; one case, where this was marked, proved fatal.)

In Group I. purpura and external hæmorrhage are constant symptoms and occur within a few days of the last injection. The patients have usually received a considerable dosage, the average number of injections in the above series being 23. Anæmia is seldom severe, reduction of platelets being the striking feature. In Group II., the agranulocytic group, fever and necrotic angina of the pharynx are the commonest signs; they tend to appear after relatively few injections and within a few days of an injection. There is only very slight lowering of the red cell count, the damage being apparently confined to the granulocytes and granulopoietic tissues. Group III., the aplastic, is the largest. In these cases all the hæmopoietic functions of the marrow are depressed. The early clinical manifestations are generally purpuric, bleeding from a mucous surface being very common. In a few cases, however, extreme pallor and weakness are the only signs. Aplastic anæmia appears as a rule only after a large number of injections, at an interval varying from two hours to over one month. A large proportion of the cases are fatal (in McCarthy and Wilson's series the death-rate was 83 per cent.) but the illness usually lasts a considerable time.

HISTORY OF A CASE

A. B., a motor-bus driver aged 29, was admitted to the Royal Infirmary, Glasgow, on May 18th, 1933, complaining of increasing weakness and pallor. He stated that during the past six weeks he had been easily tired, suffered from breathlessness on exertion, and had become extremely pale. It was ascertained that the *Spirochæta pallida* had been isolated from a small genital ulcer and that anti-syphilitic treatment had been instituted on Nov. 8th, 1932. The treatment consisted of 5·85 g. of Neokharsivan in 13 injections, 2·2 g. of bismuth metal, and Hutchinson's pill (dosage unspecified). On April 21st, 1933, four weeks after the last injection, he was found to be feverish and unwell and thereafter he became steadily weaker and paler.

On admission to hospital, apart from extreme pallor and a soft systolic apical murmur, physical examination was negative; the Wassermann reaction was negative.

there was no sign of purpura and no history of hæmorrhage. The blood count was as follows :—

Red cells	1,260,000	Polymorph	54 %
White cells ..	2,600	Lymphocytes ..	43 %
Hæmoglobin ..	20 %	Eosinophils	1 %
Colour-index ..	0·8		

There were no nucleated red cells, no reticulocytes, and in *fact no evidences of marrow activity. Platelets were very* scanty. Indirect van den Bergh reaction showed 0·25 unit of bilirubin.

The condition of the blood during the patient's stay in hospital is summarised in the accompanying Table.

Table showing Blood Count

Date in 1933.		Red cells in millions.	White cells.	Hæmoglobin.	Reticulocytes.	Transfusion.
				Per cent.	Per cent.	c.cm.
March	18	1·26	2600	20	0	—
May	24	0·84	2200	17	0	—
,,	28	1·09	1600	15	0	200
,,	29	1·12	1400	23	0	—
June	2	1·04	2800	17	0	—
,,	7	1·50	3800	15	0	200
,,	8	2·16	3200	25	0	—
,,	23	1·48	3200	20	0	240
,,	24	1·31	2000	20	0	—
July	6	1·20	3400	15	0	500
,,	7	1·70	2600	25	0	—
Aug.	11	1·13	1400	20	0	700
,,	12	2·08	2200	32	0	—
,,	28	1·66	3200	28	0	500
,,	30	1·96	2200	38	0	—
Sept.	12	2·98	4200	42	8	—
,,	25	4·01	7600	70	5	—

Improvement was very slow, but ultimately, on Sept. 25th, 1933, a blood count showed :—

Red cells	4,000,000	Polymorph	39 %
White cells	7,600	Metamyelocytes ..	7 %
Hb.	70 %	Myelocytes	4 %
		Lymphocytes ..	47 %
		Large mono.	3 %

The patient was dismissed on Oct. 10th, 1933, and has remained well so far as is known. In the early stages of the illness platelets were very scanty in the films but increased in number as the blood improved. In the course of treatment, in addition to blood by transfusion, Blaud's pill up to grs. 30 t.i.d., liq. arsenicalis up to ♏ 5 t.i.d., Campolon, Hepatex, whole liver and thyroid extract were administered. It was interesting to note that the appearance of reticulocytes in considerable numbers coincided with the administration of thyroid extract. During the earlier stages of the illness there was no evidence of marrow activity and life was maintained mainly by blood transfusions; eventually, however, the bone-marrow apparently resumed its hæmopoietic activities and the blood improved. It is suggested therefore that the case is to be regarded as one of aplastic anæmia caused by the depressing effect of neokharsivan on the bone-marrow and that it belongs to Group III. of the suggested classification. The volume of the earlier blood transfusions was small owing to difficulty in obtaining suitable donors.

MECHANISM OF PRODUCTION

These various blood dyscrasias so far recorded have occurred most frequently after the administration of neoarsphenamine; but this is probably because the drug is used more extensively than any other; in fact many authorities [8] regard sulpharsphenamine as much more dangerous in this connexion. All the organic arsenical preparations commonly used in the treatment of syphilis contain the double benzene ring and as the aplastic anæmia following these drugs closely resembles that occurring in benzene poisoning, most observers are of the opinion that the anæmia is caused by the action of the benzene group. The development of agranulocytosis and thrombocytopenia is more difficult to explain; the former may perhaps be due to a selective depressant action of the drug on the granulopoietic tissues. McCarthy and Wilson suggest that thrombocytopenia may be anaphylactoid in nature; all their cases had many injections and they consider that a sensitivity to the arsphenamines may develop gradually, and that the platelets are destroyed in the peripheral circulation. Support is given to this view by the rapid regeneration of platelets after the injections are stopped and also by the fact that in a few cases symptoms recurred whenever treatment was recommenced.

Whatever the exact mechanism of production may be, it is apparent that the organic arsenical drugs used in the treatment of syphilis can act as powerful poisons to the bone-marrow and further that their toxic action may not become manifest until several weeks have elapsed after the cessation of treatment.

TREATMENT

In the thrombocytopenic group no special treatment is required beyond discontinuing injections, for almost all the patients recover spontaneously within a few days. Where agranulocytosis or marked granulocytopenia is a feature blood transfusion is said to be of doubtful value. There appears to be no record of treatment by drugs such as pentose nucleotide, but in view of their value in other cases of agranulocytosis they should certainly be given a trial. In the aplastic cases blood transfusion frequently repeated is the only remedy with any prospect of success. Prevention is better than cure, however, and purpuric symptoms or pallor appearing during the treatment of syphilis should be regarded with grave suspicion and lead to the arsenical drugs being stopped at once.

I am indebted to Prof. W. K. Hunter for permission *to publish the notes of this case.*

PURPURA HÆMORRHAGICA CAUSED BY GOLD AND ARSENICAL COMPOUNDS

WITH A REPORT OF TWO CASES

By E. H. Hudson, M.B. Camb., M.R.C.P. Lond.

PHYSICIAN TO OUT-PATIENTS, CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST; LATE HOUSE PHYSICIAN, WEST LONDON HOSPITAL

The idiosyncrasies shown to the compounds of gold and arsenic are very similar. Both drugs commonly affect the skin and digestive system; less often they attack the hæmopoietic system, causing a reduction in the number of platelets, prolongation of the bleeding-time, and hæmorrhages, particularly from the uterus and nose. Purpura hæmorrhagica and agranulocytosis are rarer sequels.

GOLD PURPURA

Weil [1] states that the first case of gold purpura was reported in 1919. Since then others have appeared at intervals, chiefly in France, and examination of accounts of 21 of the recorded cases shows that they can be divided into two main groups :

(A) Purpura unassociated with any strong hæmorrhagic tendency. These cases recover spontaneously on stopping the injections.[2, 3]

(B) Hæmorrhagic purpura involving the whole body surface. In this type there is profuse bleeding from the mucous membranes and particularly the uterus.

The following is an account of a case of purpura precipitated by the small initial dose of a second course of aurotherapy.

CASE 1.—The patient, a woman of 21, was admitted to the Victoria Park Hospital in March 1931, under the care of Dr. F. G. Chandler, suffering from bilateral pulmonary tuberculosis. On April 9th an artificial pneumothorax was induced on the right side, and on June 10th Dr. Chandler divided an adhesion. In May and June weekly injections of 0·1, 0·1, 0·2, and 0·2 g. of Allochrysine, a total of 0·6 g. had been given. The course was not completed because of the febrile reaction ascribed to the operation. She was sent to a sanatorium.

In February, 1932, the right lung was well collapsed, but a small cavity was seen in the left upper zone. On readmission for a course of intravenous Crisalbine she was apyrexial, but the sputum contained tubercle bacilli. On March 3rd the first dose, 0·05 g. of crisalbine, was given, the only reaction being a rise in temperature from 97·2° to 98·6° F. the next day. She felt perfectly well for the next two days, and her temperature was 97·4°. On March 6th petechiæ and ecchymosis were noticed round the site of the injection and in the evening she had a profuse epistaxis.

On March 7th a fine purpuric rash appeared all over the trunk, arms, and legs; there were also petechiæ on the tongue, lips, and nasal mucosa. There was free bleeding from the gums and a large bullous hæmatoma in the buccal mucosa. The fundi were normal, the liver and spleen were not enlarged. The stools contained a large quantity of dark blood. The urine contained no blood or albumin. The temperature was 98·6°, and the pulse-rate 100. The catamenia had started on March 5th, although not expected until the 8th. The loss was profuse and lasted a fortnight instead of the usual four days.

The patient was given glucose 4 oz. daily, Liveroid ½ oz. three times a day, and minced liver ½ lb. daily by mouth; also six injections of 20 c.cm. horse serum together with 2 c.cm. hæmostatic serum intramuscularly at six-hourly intervals. On March 8th and 9th she had a profuse epistaxis but no fresh petechiæ. An injection of 3 c.cm. of 10 per cent. solution of calcium chloride was given intravenously. On March 10th there were many fresh petechiæ: temperature 99·4°, pulse-rate 104–120. On the 11th the vaginal loss was more profuse, and two further doses of hæmostatic serum and horse serum were given. In the evening her condition became much worse, and a transfusion of 500 c.cm. of citrated blood, Group II., with 50 c.cm. of 25 per cent. glucose was given, the donor being the patient's sister. From now on there were no fresh petechiæ the oral bleeding stopped, and the patient made slow improvement until her vaginal loss ceased, after which she improved rapidly. The blood counts are shown in Table I.

Outcome.—The tuberculosis advanced steadily and the patient died from this nine months later, there having been no recurrence of purpura.

ARSENOBENZOL PURPURA

Bamforth and Elkington[4] in 1931 reviewed 15 recorded cases of arsenobenzol (arsphenamine) purpura, the first of which appeared in 1917; they also reported 4 of their own. The second case is strikingly similar to the case of gold purpura described above.

The patient, a man aged 40, was admitted to the West London Hospital in March, 1931, under the care of Dr. J. Burnford. He had an aneurysm of the aorta and the axillary artery, and his Wassermann reaction was strongly positive. Potassium iodide grs. 30 daily was given by mouth and intramuscular injections of Sulfarsenol (sulpharsphenamine). A total of 4·3 g., given between Jan. 11th and March 28th, completed the course. Four hours after the final injection of 0·6 g. he noticed a rash on his arms and legs. Toxic symptoms had not been observed up to this time, though he later admitted that he had felt unwell after the last four injections.

On admission to hospital on March 30th the distribution and extent of the lesions was almost exactly the same as in the case of gold purpura. The extravasation of blood round the site of the last injection was very extensive. The patient was bleeding freely from bullous hæmatomata in the buccal mucosa. Neither the liver nor the spleen was palpable, the fundi were normal, and the urine contained a trace of arsenic but no albumin or blood. Intravenous glucose (50 c.cm. of 25 per cent. solution) was given on admission. Liver. Liveroid, Coagulin Ciba (2½ per cent. solution by mouth), and hæmostatic serum by injection had no apparent effect in arresting the hæmorrhage, and fresh purpura appeared until a blood transfusion was given, after which all bleeding ceased within a few hours and he made a rapid and uneventful recovery. The blood counts are seen in Table II.

Outcome.—In May, 1935, his private doctor, Dr. J. A. Butler, wrote: "The patient is tolerably well; the aneurysm has not apparently progressed and there has been no jaundice or symptom of injury to the liver.

* Blood transfusion 650 c.cm. Group III. † With punctate basophilia. Occ. = occasional.

The uterine condition was treated by intravenous injections of Trypaflavine and Novalgin combined with glycerin and Protargol vaginal tamponage. It improved rapidly, but the joint affection gradually became worse. On March 9th she received dental treatment for a marginal gingivitis, but still the joint condition progressed.

On April 28th the patient was referred to me as a case of gonorrhœal arthritis. When I first saw her she was lying in bed with both knees fully flexed, thighs flexed on the abdomen, and ankle-joints extended. The muscles of thighs and calves were markedly wasted. The right arm was flexed at the elbow, and wrist and hand were in the claw position. She was greatly emaciated and utterly miserable. There was complete incontinence of fæces and urine. I was unable to move any of the joints affected on account of spasm and pain. Movement under anæsthesia was contra-indicated because of the risk of fracturing the bones. It was considered that the origin of the disease was much more deeply seated than a mere polyarthritis, and accordingly her cutaneous sensations were tested. Owing to the lack of coöperation of the patient the tests were unsatisfactory but sufficient evidence was available to prove paræsthesiæ of both legs and arms.

Next day lumbar puncture was performed. The first tap was made between the 2nd and 3rd lumbar spines, but no fluid dripped from the needle. The 1st lumbar space was then tried with similar result and the 3rd space was tapped, still with negative result. A syringe was attached to the needle and about 2 c.cm. of cerebro-spinal fluid was aspirated with difficulty. The Wassermann and Kahn tests on the fluid were both negative. The fluid was clear, giving a cell count of 2 to 4 per field, chiefly lymphocytes. The total protein was 50–55 with only a trace of globulin.

A tentative diagnosis of chronic adhesive meningitis was made. In order to clear up the diagnosis cisternal pucture was performed on May 2nd under local infiltration and 5 c.cm. of lipiodol was injected. The patient was propped up in the erect attitude for 20 minutes and a radiogram taken. Her condition was very poor during this period. The pulse was rapid and there was profuse sweating and general symptoms of collapse. She recovered somewhat after return to bed, the head being propped up to prevent the lipiodol gravitating to the brain. The following day her general condition had improved, but she complained of severe pain on the right side of the head, neck, and body.

The radiogram showed a block in the subarachnoid space between the 1st and 4th lumbar vertebral levels. The block was incomplete, showing a ragged lower margin and a fine hair-like canal leading down to the level of 3rd lumbar vertebra, thus permitting some of the lipiodol to pass down into the sheaths of the nerve-roots.

I did not see the patient on the day after the lipiodol injection, but on the second day after it I was astonished to find her lying flat on her back with the legs fully extended and flaccid. In this short space of time a marked spastic paresis had been transformed into a flaccid paresis, but most important of all, she had regained complete control of her sphincters, both vesical and rectal. From now on her general condition improved rapidly and her outlook became much more cheerful.

The muscle reactions to galvanic and faradic stimuli were tested and all muscles were found to give a slight reaction, especially to faradic stimuli. The patient was instructed constantly to attempt to move her limbs, and on May 6th she was able to flex the knee and thigh ever so slightly. This fact, however, had an obvious psychological effect on her and she thereafter became a willing coöperator in the treatment. Massage and electrical treatment were given twice daily, and in addition she was put on an iron tonic. The control of the sphincters was maintained except occasionally when the bowels were very loose. On May 21st a set of pulleys was fixed to the foot of the bed and a foot-plate with cord attached was bandaged to the sole of each foot. A weight of 2 lb. was attached to each cord and the patient was advised to flex the legs against the suspended weights. The muscular tone and power increased rapidly under this régime. In addition to the leg movements she was now able to move the right arm freely, although coördination as tested by touching the tip of the nose with the eyes closed was deficient. She put on weight rapidly and was completely changed from her former inert picture of misery to a cheerful and alert person.

On June 3rd—that is one month after the injection of the lipiodol—she was able to sit up in bed and feed herself with solid food, which she had been unable to do for months. The power and coördination of her arm did not, as yet, permit her to carry liquids to the mouth. Two weeks later she was able to walk round her bed holding on to the frame. She still complained of a feeling of weakness and pain on the right side of the neck and right half of the body. I believed the pain to be due to a form of muscular rheumatism, from the long period of disuse, and put her on small doses of sodium salicylate, tincture of opium, and digitalis which appeared to produce considerable improvement.

On July 6th she was able to walk about the ward with the aid of crutches. As she did not appear to improve much after this period, I decided to try the effect of repeating the lipiodol. Consequently, on July 19th the cisterna magna was again punctured and 5 c.cm. of lipiodol injected. The patient showed no signs of distress on this occasion. She was again radiographed and the canal was seen to have opened up considerably although the outline in the lumbar region was still somewhat ragged and there was still a constriction opposite the 4th lumbar vertebra. She was confined to bed for three days after the injection and then allowed up. Progress was now rapid and uninterrupted. She walked out of the hospital, discharged, on August 18th. Her weight on July 29th was 56 lb., and on the day of discharge 68 lb.

THE SECOND CASE

A male Tamil, aged 20, was admitted to hospital on July 6th with a history of having fallen from a tree a distance of about twenty feet. He had lain unconscious in the rain for some hours before being picked up. On admission he had abrasions on the inframaxillary region, great pain in the epigastrium, and tenderness at the base of the thorax and right hypochondrium. The abdomen was slightly distended, but there was no loss of liver dullness. The alæ nasi were moving synchronously with respiration.

I was called to see the case as a possible rupture of the liver, but decided from clinical examination that the condition was concussion of the spinal cord. The patient was kept quiet with morphine, and rectal and hypodermic salines were administered to counteract shock. On the second day after admission the temperature rose to 104·5° F., with respirations 38 and pulse-rate 120, and he had a rigor. This sequence recurred the following day, and on examination of the lungs both bases were found to be dull with fine crepitations. His breathing became very laboured and a pleuritic rub developed. Fluid appeared in the right pleural cavity and his condition became so alarming that his relatives were sent for. The chest was aspirated and 200 c.cm. of fluid resembling pure blood was removed. His general condition gradually improved, but on July 16th he developed frequency of defæcation and was constantly asking for the bed-pan. Two days later he had difficulty in passing urine and had to be catheterised. The following day he became incontinent of fæces with retention of urine and complained of weakness in the right leg. At this period he was very morose, and would not speak nor answer questions.

On July 19th lumbar puncture was attempted but resulted in a dry tap, and because of his condition no further attempts were made on this occasion. On July 29th lumbar puncture was repeated first in the 1st lumbar space, then in the 2nd, but both resulted in a dry tap. The 4th space was next tried with similar result, but with the aid of an aspirating syringe five drops of yellowish-green pus were obtained. This material was sent to the bacteriologist who returned his findings as Gram-negative bacilli of unknown strain.

Having recollections of our previous case I decided to try the effect of lipiodol via the cisterna magna and this was done under local anæsthesia on August 1st. Five c.cm. was injected and a radiogram taken. This showed the lipiodol scattered about in small globules instead of forming a solid mass outlining the spinal theca. Meanwhile, the loss of control of the sphincters had continued, but on August 3rd—that is two days after the injection of lipiodol—he was able to pass water by himself, although for a few days after, the catheter had to be passed occasionally. Thereafter he regained complete control of bladder and rectum and he began to move the right leg.

The patient was put on a highly nutritive diet with cod-liver oil and tonics and improved rapidly. By August 24th he was walking about with the aid of crutches, and a week later he was able to walk unaided although there was still some weakness and a consequent limp with the right leg. He was discharged from hospital fit on Sept. 15th, able to walk freely but with some weakness of the right leg on running.

COMMENT

These two cases appear to open up a new field in the treatment of subacute and chronic infections of the spinal meninges. In my opinion the good results of injecting lipiodol are due to a chemical inflammation superimposed on the chronic condition, causing absorption of the adhesions, and of any blood clot or pus present, with relief of the œdema of the nerve-roots. Lumbar or cisternal puncture is always followed by a reaction in the cerebro-spinal fluid, but judging from the almost immediate benefit in both these cases after the injection of lipiodol, I am convinced that the iodised oil was the primary factor in producing a return to health.

According to a recent paper by Vincent, Rappoport, and Berdet,[1] remarkable results have been obtained in such conditions as traumatic injuries to the meninges by the simple injection of air by the lumbar route. By this method they claim 70 to 80 per cent. cures in post-traumatic vertigo and headache. In traumatic epilepsy good results have also been obtained. In the encephalopathies of infants, encephalitis, tabes, and general paralysis the results are negative. In their opinion the passage of air in the subarachnoid space dilates the space by mechanical pressure where the canal is narrowed by adhesions. This permits the reduction of œdema which results from congestion, due to kinking of the vessels, particularly the veins, by the adhesions, thus allowing a return to normal of the cerebro-spinal fluid and vascular circulation. According to Craig,[2] lipiodol should not be used in frank inflammatory lesions because of the irritative action on the meninges. I have not had an opportunity of trying lipiodol in pathological lesions of the cerebral meninges, but I would not hesitate to make use of it in selected cases, since Laruelle has used it in a number of cases for encephalography for diagnostic purposes, without untoward results.

SUMMARY

Two cases of localised chronic inflammatory meningitis are reported, both having a certain amount of paresis with loss of control of rectal and bladder sphincters. In both of them lipiodol was injected into the cisterna magna primarily for diagnostic purposes, and in both of them the symptoms were alleviated in an almost miraculous way, with complete cure later.

I have to acknowledge my thanks to Dr. Apparajoo for his careful records and attention to the patients, and to Dr. J. S. Webster, radiologist, General Hospital, for the radiograms.

Since completing this report I have found a reference by Barré[3] to a case of arachnoiditis in which Guillain obtained excellent results by a single injection of lipiodol. No further particulars are given and I am unable to obtain the original paper.

CLINICAL AND LABORATORY NOTES

A CASE OF BOTULISM

WITH A NOTE ON THE BACTERIOLOGICAL EXAMINATION OF THE SUSPECTED FOOD

By C. Rickword Lane, D.M. Oxon.
PATHOLOGIST TO THE HAMPSTEAD GENERAL HOSPITAL; AND
T. E. Jones-Davies, B.A. Camb., M.R.C.S. Eng.
HOUSE PHYSICIAN AT THE HOSPITAL

In view of the rarity of botulism a brief record of the symptoms, signs, and course of the first of the present series of cases, together with the subsequent confirmatory investigations, may be of interest.

A woman, aged 50, was admitted to hospital on August 5th with a history of having eaten some vegetarian nut brawn at 9.30 the previous night. On the morning of admission at 9 A.M. she was found by her brother in a rather dazed condition. The patient complained that she was unable to see clearly or talk normally, and later she had difficulty in swallowing. She also vomited and had several fainting attacks. The bowels were opened once in the course of the morning, but there was no diarrhœa. Her brother, aged 69, also took some of the same food but not as much as his sister.

On admission in the afternoon the patient was obviously distressed and cyanosed but had no pain. Her temperature was 97° F., pulse 65, and respirations 20. She answered questions only with the greatest difficulty. There was an obvious bilateral ptosis and the eyelids had to be lifted to see the state of the pupils. Strabismus was marked, the left eye looking downwards and outwards, the right eye looking directly outwards. The pupils were centrally situated, medium and equally dilated. The left pupil reacted to light normally but the right one only very sluggishly. The seventh nerve was unaffected. The soft palate was paralysed. The knee-jerks were present and the plantar reflexes flexor. There was no obvious enlargement or dilatation of the heart; the sounds were feeble and there were no bruits. The movements of the chest were irregular, spasmodic, and incoördinated. The bases of both lungs were dull to percussion and over these areas moist râles could be heard. There was no localised mass or tenderness in the abdomen.

Taking into account the definite physical signs present, together with the history of having eaten the particular food mentioned, botulism was diagnosed. Although the extreme rarity of the disease was fully realised, a special messenger was sent to obtain some anti-botulinus serum from the special department of the Ministry of Health at Colindale, and the medical officer of health was informed forthwith.

The patient's condition became rapidly worse. Her cyanosis increased, air-hunger set in, and the pulse increased to 120 beats per minute before she died 23 hours after ingestion of the suspected food—9½ hours after the first symptom made itself manifest.

DISCUSSION

In arriving at such a diagnosis the possibility of bacterial food poisoning had to be excluded. The absence of diarrhœa and the presence of the definite signs were sufficient to do this. The diagnosis of encephalitis lethargica or poliomyelitis was unlikely owing to the absence of fever; moreover, consciousness until three-quarters of an hour before death, from an infection in the brain sufficient to account for such marked cranial nerve signs, would hardly be possible in a true encephalitis. Again an encephalitis of so fulminating a type would more likely be of the hyperkinetic than the amyostatic hypokinetic and somnolent varieties. No history of the patient having taken any drugs could be obtained.

The incubation period in this case seems to be shorter than the average time quoted by G. Leighton (1924) in the Loch Maree cases. The shortest period before the onset of symptoms in that series of eight cases was 14 hours, while death occurred in 17 hours in one case, the duration of the disease was longer in the other cases. The statement that vomiting denotes an unusually heavy dose of toxin and usually presages a fatal termination (Mathews [1]) seems to be well borne out in this case.

The brother had a heart attack and died soon after hearing of the death of his sister. Shortly before he died he complained that he was unable to speak properly and that his voice seemed unfamiliar to him. At that time there were no ocular symptoms. The difficulty in speech may be significant as he stated quite definitely that he had not taken so much of the suspected food as his sister had. Symptoms of the disease would thus be expected to appear later in his case but might have been masked by the obvious mental distress and precordial pain.

BACTERIOLOGICAL INVESTIGATION

The food consisted of a number of vegetables, including peas, and particles of carrot and other unrecognisable vegetable material. As it was believed that experiments designed to prove the presence of toxin in the food itself were being undertaken at the request of the food inspector, and as only a small quantity of the food was available, it was decided to attempt to grow *B. botulinus* from it and not to attempt to prove the presence of the toxin.

A portion of the food was emulsified in sterile normal saline. The resulting suspension was heated to 80° C. for half an hour, and then thoroughly mixed with melted glucose nutrient agar and glucose nutrient gelatin and grown anaerobically at room temperature. The weather was very warm at this time and growth was obvious in three days although there was not much gas production.

Subcultures were made into glucose nutrient broth. No growth took place in this, possibly because the weather was now much cooler, although some growth must still have been possible as the gelatin cultures which had not liquefied during the first three days liquefied during this period. Subcultures were now made into human serum glucose nutrient broth and incubated anaerobically at 37° C. Growth was apparent in two days and a fresh glucose agar shake put up at the same time showed growth with disruption of the medium.

The serum broth cultures were allowed to grow for a week and then filtered through an L 5 candle. Nine guinea-pigs were injected: one with 1 c.cm. of the serum glucose broth used for preparing the toxin and incubated anaerobically in the same jar as the cultures were grown in; one with 1 c.cm. of undiluted toxin; one with 1 c.cm. of toxin diluted 1 in 100 with normal saline, another with 1 c.cm. of 1 in 1000 toxin, and another with 1 in 10,000 toxin. Four other guinea-pigs were injected with like amounts of toxin and toxin dilutions, and in addition 2 c.cm. of polyvalent anti-botulinus serum obtained from Burroughs Wellcome and Co.

All guinea-pigs given serum survived, as also did that injected with the control serum broth. Those inoculated with 1 c.cm. of undiluted toxin, 1 c.cm. of 1 in 100 and 1 c.cm. of 1 in 1000 toxin died within 18 hours. That inoculated with 1 in 10,000 toxin died in 2½ days, death being preceded by dyspnœa, loss of resistance of abdominal muscles, and paresis of the hind limbs. At post mortem none of the animals that died showed any obvious signs except congestion of the superficial cerebral vessels.

No attempt has yet been made to determine the type of *B. botulinus* responsible as so far it is not certain that the growth is pure.

We are indebted to Dr. A. J. Scott Pinchin under whose care the patient was admitted for permission to publish this case; also to Dr. C. Kitkat for information of the earlier condition of the patient and for sending the suspected food to the hospital.

SEPTICÆMIA DUE TO BACILLUS FÆCALIS ALKALIGENES

By W. Moir Brown, M.B., F.R.C.S. Edin.
ASSISTANT SURGEON TO HEREFORDSHIRE GENERAL HOSPITAL; AND
W. Stewart, M.D. Glasg.
CONSULTING PATHOLOGIST TO THE HOSPITAL

A fair number of cases of infection by *B. fæcalis alkaligenes* have been described. As a rule it seems to simulate infection by the typhoid-paratyphoid group. Gracey [1] records two cases from Malaya.

Case A.—Female aged 26. History of three days' fever and vomiting. Patient was six months' pregnant, and labour set in five days after admission. This was followed by rigors and high temperature. Metastatic abscesses developed in the left thigh and left side of the neck. Two months later blood culture gave a growth of *B. fæcalis alkaligenes*. The Widal reaction was negative and the patient ultimately recovered.

Case B.—Patient was a man aged 26, with swelling of the testicle and epididymis of four days' duration. Abscess of the testicle followed a fortnight afterwards. Examination of the blood and stools was negative. A week later blood culture showed *B. fæcalis alkaligenes*. Similar growth was obtained from the pus of the testicular abscess. Blood-serum from the patient gave positive agglutination against typhosus O up to a dilution of 1–200. This patient also recovered.

Zinsser and Russell [2] quote a case of severe gastro-enteritis as due to this organism, and Gatewood [3] records a case of meningitis in which it was isolated from the cerebro-spinal fluid. The meningitis had followed a cranial operation for a traumatic cyst of the brain due to a fracture of the skull and the patient recovered. Slaboziana and Nasta [4] record fatal peritonitis in twins.

One died 36 hours after delivery and the other when 5 days old. The organism was obtained from abdominal puncture during life. At the autopsy on one of them there was found peritonitis with adhesions, and infarction in the stomach and spleen, but no lesion of the intestine could be made out. Before the confinement the mother had been healthy and labour was normal. The Widal reaction of the blood-serum was negative to typhoid, paratyphoid A, B, and C, and Gaertner, aertrycke, and Morgan bacilli. It is concluded that a saphrophytic organism in the mother had become pathogenic in the fœtus.

Anderson[5] reports two cases which simulated rheumatic fever; there was a previous history of rheumatism in both, but they did not respond to salicylates. Blood cultures yielded *B. fæcalis alkaligenes*, and the patients made complete recoveries.

The case which came under our observation was that of a woman aged 33, the wife of a pig-breeder. The illness followed upon the labour of a first pregnancy. Delivery had been by forceps. After the confinement and while still in the nursing-home she developed a cracked left nipple. She was discharged from the nursing-home in fourteen days, but after her discharge the left breast became painful and swollen and there was irregular fever.

A month after the confinement she was admitted to hospital with a temperature rising to 100° F. in the evening accompanied by slight headaches. The left breast was œdematous with a small fluctuating mass in the centre of the œdematous area. The breast was opened three days later when a little thin serous pus was obtained. Rubber drains were inserted, but the expected improvement did not occur and very little pus drained from the wound. The temperature became higher and more irregular (99–105° F.) with rigors. The left breast was again opened and drainage-tubes inserted in the fascial space underneath the breast proper. No pus was obtained and none came away in the drainage-tubes. Fluctuating temperature and rigors continued. Erythematous areas appeared over the left arm, shoulder, back, and groin, suggestive of erysipelas but with no raised margins. These yielded to treatment with glycerin and ichthyol. Slight delirium developed in the evenings. The liver and spleen were not palpable and no tenderness or rigidity in the abdomen was evident. There was no suggestion of enteritis nor of uterine infection at any time during the illness. At various times she had treatment by Collosol iodine, intravenous Mercurochrome, and intravenous glucose. The temperature fell by lysis and a month after admission it was normal; but the operation wounds in the left breast still discharged thin serous pus in small amount.

Throughout the illness there was no abnormality in the urine except a slight trace of albumin and a few epithelial casts. Ten days after admission a blood count showed:—

Red cells ..	2,700,000 per c.mm.	Polymorphs ..	80 %
White cells ..	25,300 per c.mm.	Lymphocytes ..	18 %
Hæmoglobin . ..	43 %	Basophils ..	2 %
Colour-index . ..	0·8	Eosinophils	2 %

Culture from the blood at the same time gave a pure growth of coliform bacilli having the following characteristics: very faint motility; no fermentation in glucose, maltose, mannite, lactose, sucrose, salicin; and no liquefaction in gelatin. A swab taken from the operation incisions in the breast showed organisms of the same type. The Widal reaction of the blood-serum gave a positive agglutination to *typhosus* O in dilutions of 1–25 and 1–50. The agglutination was completely negative to *typhosus* H, paratyphoid A, B, and C, and *Brucella abortus*. The serum was further put up against suspensions of—

Bact. aertrycke (O sp.) ..	Slight positive agglutination in dilutions of 1–25 and 1–50.
Bact. aertrycke (H sp.) ..	Gave similar results.
Non-specific salmonella..	Positive in dilution of 1–25.
Bact. gaertner	Positive in dilutions of 1–25, 1–50, 1–125, and 1–250.
Bact. newport	Slightly positive in dilutions of 1–25 and 1–50.

All the other dilutions gave negative results.

The bacillus obtained from the blood was put up against the sera of *aertrycke* O and H, non-specific salmonella, *Gaertner* (H), and *newport*, all with completely negative results. From these investigations it was clear that the organism was *B. fæcalis alkaligenes*.

The husband was a pig-breeder who maintained a fairly large stock of pedigree pigs. In his herd there had previously been outbreaks of what were veterinarily termed infectious necrotic enteritis, swine-plague, white scour, and abortus fever. One of us had the opportunity of examining the premises and carrying out a few more investigations there. The pig-fold was an oblong structure with the pig-sties arranged around the sides. The conditions found were exceedingly primitive and showed gross neglect. The manure from the pigsties had been allowed to accumulate in the fold for many months and the liquid part to drain away as best as it could. The pigs were in very poor condition and many showed extreme malnutrition. The domestic water-supply came from a shallow well which was situated close to a corner of the pig-fold. It could not possibly escape gross contamination from the fold. Three weeks after the patient had been admitted bacteriological examination of the well water showed:—

Number of organisms capable of growing on agar at 37° after two days' incubation ..	2,220 per c.cm.
Number of organisms growing on agar at 22° C. after three days	10,200 ,,
Probable number of *coli aerogenes* organisms in 100 c.cm. of original water	900.

No. *B. welchii* were isolated, and no *B. fæcalis alkaligenes* found—a somewhat surprising finding in view of the conditions—but examination of the sewage from the fold showed the presence of *B. fæcalis alkaligenes*. In addition we were able to examine one of the young pigs. The intestines though free from visible lesions contained numerous large round worms and cultures taken from the ileum gave growth of *B. fæcalis alkaligenes*. Those from the cæcum and spleen were negative.

The gross contamination of the domestic water-supply in this case might be put forward as a possible source of the infecting organism, though the bacteriological examination of the water did not reveal it. The presence of the organism in the normal intestine has also to be remembered. Investigation has shown the presence of *B. fæcalis alkaligenes* in 19 per cent. of a total of 386 healthy soldiers and in 71·5 per cent. of 126 who were suffering from catarrhal conditions of the bowels. The relatively lowered resistance of the bowel during the puerperium might allow easier access to the invading organism.

Muir[6] states that the organism in question is apt to appear in the intestinal flora in the later stages of bacillary dysentery and disappears as recovery takes place. He points out that the evidence is suggestive that these organisms are pathogenic entities which may be responsible for diarrhœal conditions in young subjects and in adults.

Although the clinical symptoms in these cases are fairly severe the mortality-rate is apparently low and the condition seems to respond well to general treatment. The organism seems to have little or no effect on animals inoculated with it. Association with pregnancy has been noted in other cases, and it was presumably a factor in this case. The patient made a complete recovery and so far there has been no suggestion of recurrence.

EAST GRINSTEAD'S NEW HOSPITAL.—This new hospital, which is being erected at a cost of £24,000, will be completed and equipped by the New Year. It replaces the existing cottage hospital which has become too small for the needs of the district. Princess Helena Victoria has promised to perform the opening ceremony.

REVIEWS AND NOTICES OF BOOKS

Head, Heart and Hands in Human Evolution

By R. R. MARETT, M.A., D.Sc. Oxon., Rector of Exeter College, Oxford. London: Hutchinson's Scientific Books. 1935. Pp. 303. 10*s.* 6*d.*

OUT of his wealth of experience and learning and in a most agreeable manner the Rector of Exeter College has here put together a number of essays and addresses on the thoughts, habits, and accomplishments of primitive man as revealed partly by the study of prehistoric remains and partly by the current life of savage peoples. The tale he tells so well is of great interest, and readers will be tempted to go further than he does—to link what he says with the doings of animals on the one hand and our own vagaries on the other. They will do so with profit, for running through his descriptions and comments are two main theses—that we must take curious actions as we find them and judge them by their intentions rather than by their apparent effects, and that natural man is not a practical fellow but a mystic with whom moral values weigh more than what our sophisticated scale counts as material advantages. As far as we may judge it, the life of palæolithic man or of the Fuegians may seem to be hardly tolerable; yet, as Dr. Marett shows, they knew how to make it worth while by play and fun and by an intimate contact with a spiritual unknown. Clothes did not start with a liking for being warm but with a fancy for dressing up, dancing is an anticipation of civilised litanies, and through it all is a passion for friendliness. Our only regret is that some parts of the book are not more amply treated, especially in the last section on arts and crafts, where we learn, e.g., that the principle of the Diesel engine was known long ago to wild men in Indonesia. What too is the real rationale of the peculiarly human habit of cooking food? More time and trouble are perhaps consumed on that occupation than on any other human activity, but no explanation of why we do it is wholly convincing and satisfying: possibly it is for the fun of making a fire, or is it to denature the proteins?

La vaccinothérapie dans l'asthme bronchique

Ses Indications. By FEDERICO NITTI, l'Hôpital Bichat et le Service des Vaccins de l'Institut Pasteur. Paris: J. Peyronnet et Cie. 1935. Pp. 141. Fr.12.

THIS is a critical and readable essay on the value of vaccines prepared from the sputum in the treatment of asthma, and though it is based on a slender personal experience it is supported by a good bibliography. Dr. Nitti believes that respiratory infection is common in asthmatics and that it is an important factor both in the initiation and the prolongation of the disease. He considers it unlikely that the proteins of the bacteria act as irritants, to which the patients react in the same way as they react to pollen, dander, or similar allergens, for skin tests show that asthmatics are not more sensitive to bacteria isolated from the respiratory tract than are chronic bronchitics or normal individuals; and moreover very much stronger skin reactions can be obtained with organisms such as the typhoid bacilli, which certainly have nothing to do with the disease. The explanation is rather that the chronic bronchitis acts as an irritable focus, which favours the occurrence of the paroxysms, and is also perhaps responsible for the persistent dyspnœa and other pulmonary phenomena which may remain between the attacks. On this account vaccine treatment is of value only in asthma complicated by bronchitis, and the patient remains a potential asthmatic even though the respiratory infection becomes quiescent. The respiratory flora of asthma is identical with that of chronic bronchitis, and is remarkably constant even though the condition is improved by vaccines. In the sputum *Streptococcus hæmolyticus* and *viridans* and pseudo-meningococci predominate; in the nasal secretions the staphylococcus is the chief organism. It is essential that the sputum should be obtained fresh during or just after a paroxysm, and it is best for it to be expectorated in a sterile Petri dish at the laboratory itself. Details are given of the mode of preparation of the vaccines and the frequency and size of the doses, which are injected intradermally. Of the author's small series of patients two-thirds were much improved. The writing throughout is so modest and disarming that many readers will doubtless be inspired with fresh enthusiasm for the vaccine treatment of asthma, in spite of a lurking suspicion that the therapeutic action of vaccines in any bacterial infection still awaits a convincing demonstration.

Recent Advances in Diseases of Children

Third edition. By WILFRED J. PEARSON, D.S.O., M.C., D.M., F.R.C.P., Physician in Charge of Children's Department, University College Hospital; Physician to the Hospital for Sick Children, Great Ormond-street; and W. G. WYLLIE, M.D., F.R.C.P., Physician to Out-patients, Hospital for Sick Children, Great Ormond-street; Physician to the Hospital for Epilepsy and Paralysis, Maida Vale. London: J. and A. Churchill Ltd. 1935. Pp. 566. 15*s.*

THE series to which this volume belongs is one which has led us to expect a high standard of scholarship and a comprehensive review of the most recent work on the subject dealt with. Pædiatrics is perhaps a rather wide field for satisfactory survey in a book of this compass, but in comparison with its fellows this work is somewhat disappointing. A great deal of matter has been included which is too elementary and at the same time too irrelevant to justify the title "recent advances." Whilst any progress in medicine is admittedly based on a sound knowledge of physiology, this hardly appears the place for a rather tedious and not very original recapitulation of elementary biochemical principles. Similarly, some at least of the clinical descriptions, though unimpeachable, might equally well have been written in 1900 as in 1935. It is only fair to say, however, that the authors would admit this freely; their aim has been to give "a connected outline of the diseases of childhood, emphasising modern conceptions of pathogenesis and recent advances in treatment." Its appearance in a third edition, which has been considerably revised, particularly the chapters dealing with diabetes and immunisation, shows that there is a considerable demand for a book of this character, and if too scientific an approach is not expected, the reader will find much of interest in it. The chapters dealing with the diseases of the chest and of the nervous system seem to us the most useful. Some of the statements made with regard to diathesis f various types are based on rather nebulous data nd will hardly find general acceptance. The production of the volume is uniformly excellent, and he publishers are particularly to be congratulated n the large number of radiograms they have been ble to include.

Infections of the Urinary Tract

By T. E. HAMMOND, F.R.C.S., Surgeon to the Royal Infirmary, Cardiff; Consulting Urologist, the Welsh National Memorial Association. London: H. K. Lewis and Co., Ltd. 1935. Pp. 250. 10*s.* 6*d.*

A LARGE portion of this book is devoted to an exposition of the author's views on the nature of infection, in an attempt to correlate infections of the urinary tract with those occurring elsewhere in the body. Mr. Hammond believes that the type of disease occurring in any individual depends as much on the constitution of that individual as on the nature of the infecting organism. He recognises two main classes of abnormal constitution, the hypersthenic and the hyposthenic. The former reacts vigorously to infection, being liable to staphylococcal disease; the latter is said to be more subject to infection with *B. coli*, with a tendency to a poor reaction and chronicity. Stress is laid upon the reactions of the individual to therapy as well as to infection. The author claims that the drugs used as urinary antiseptics act not on the invading organisms but on the tissues of the patient, stimulating their defence mechanisms. Hexamine and the ketogenic diet are thus both believed to exert their favourable effect by direct action on the cells of the central nervous system. The descriptions of the various forms of infection of the urinary tract are clearly the result of a wide experience in urology, and the theories propounded in this book, though unorthodox, are the outcome of much thought devoted to the problems of infection.

Lactobacillus Acidophilus

Its Therapeutic Application. By LEO. F. RETTGER, Ph.D., LL.D., Professor of Bacteriology in Yale University; MAURICE N. LEVY, M.D., LOUIS WEINSTEIN, Ph.D., and JAMES E. WEISS, Ph.D., Research Fellows in Yale University. New Haven: Yale University Press. London: Humphrey Milford, Oxford University Press. 1935. Pp. 203. 11*s.* 6*d.*

THOSE who are specially interested in sour milk therapy will welcome this book. It begins with a series of chapters dealing with the various types of lacto-bacilli and the influence of temperature and other important factors on the growth of the organism. The authors make quite clear the extreme difficulty of isolating the various members of the group, and indicate many points on which precision is impossible even to-day. They are also at pains to show how easily the viability of acidophilus milk can be affected by various adver [illegible] influences and how often therapeutic results [illegible] appoint owing to a diluted or delicate [illegible] mployed. It is to be noted that the [illegible] quart daily of a highly viable acidop[illegible] the necessary minimum dosage i[illegible] are to be obtained. About the type of case [illegible] is likely to benefit from sour milk therapy the authors are rather vague, but apart from somewhat ambiguous conditions such as chronic intestinal stasis they appear to consider that it is in mucous colitis and non-specific ulcerative colitis that the most promising results are secured; 75 per cent. of cases of mucous colitis improved notably but the symptoms appear to have returned in all of them as soon as the milk treatment was discontinued. Less unsatisfactory results were obtained in chronic ulcerative cases; in seven out of eight of such cases the diarrhœa, mucus, blood, and pus disappeared, and although constipation followed cessation of the treatment there was no return of the more alarming symptoms.

We confess that admiration of the fairness and detailed work of the authors of this volume is tempered by disappointment at the very modest claims which they are able to make for a remedy which has interested the public and the profession now for a great number of years.

Manual of Medicine

Fourth edition. By Sir STANLEY WOODWARK, C.M.G., M.D., F.R.C.P., Physician and Lecturer on Medicine, Westminster Hospital; Senior Physician to the Royal Waterloo Hospital. London: Humphrey Milford, Oxford University Press. 1935. Pp. 619. 15*s.*

THIS book is intermediate in size between a text-book and a synopsis, and its style varies from a clipped prose to frank notes and enumerative lists. It doubtless serves a very useful purpose, purveying information to the student whose time is short or who lacks the capacity for making his own notes from a larger text-book. When so much material of varying importance is compressed into so small a space, the perspective is distorted and a proper and graded distribution of emphasis becomes impossible. This is particularly noticeable when treatment is being described. Apart from this limitation, imposed by its nature, the book follows fairly well the lines of accepted teaching, and has been brought up to date. Surprises, however, are not difficult to find, such as the statement that chronic gastric ulcer is commonest in males between 30 and 60 and that alcoholism probably plays a part in its causation, and the further remark that it is "almost invariably" situated at the pylorus. There are a few simple and useful illustrations, chiefly neurological, and a section on insanity is included.

Play in Childhood

By MARGARET LOWENFELD, M.R.C.S., L.R.C.P., Co-Director, Institute of Child Psychology. London: Victor Gollancz Ltd. 1935. Pp. 345. 8*s.* 6*d.*

THE approach to child psychology—normal and abnormal—has till recently been a twofold one. On the one hand there have been the laboratory researches into intelligence by tests, and close observational work of the child mind in action. The classification of clinical disabilities has been unproductive, but psychopathology has opened a new horizon in that it stressed the infantile origin of neurosis and the phantasy life of the child. It was soon seen that while psycho-analysis would reveal mental mechanisms in adults by free association, similar mechanism in children could only be revealed by free play activity in which phantasy was in operation and through which the child played out its experiences and its attitude to its environment. [illegible]hile admitting th the play technique had its true origin in the wo of such analysts as Hug Hellmutt, Anna Freud, and Melanie Klein, Dr. Lowenfeld has worked out a technique of her own, and this volume attempts to give an account of the method and of its findings. The volume is very liberally illustrated with case material and shows the author's enthusiasm and faithful clinical approach. The fascinating "worlds" that children erect in their sand trays are described and interpreted, and the author for the sake of clarity has described the child's activities with phantasy play, and play as repetition of experience, as realisation of environment, and as preparation for life. Those who have similar experience of child play in normal and abnormal subjects will be at one time astonished at the author's daring and at another amazed at her reserve in not going deeper into some of the reactions she records. The analysts will itch to make further interpretations, and the laboratory type of observer will shrink from some of her deductions. But the book is sufficiently documented to reward careful study, even by those who will feel that the author falls between two stools.

1. Patient and Doctor

By Sir HENRY B. BRACKENBURY, M.D., LL.D., M.R.C.S., Vice-President (late Chairman of Council), British Medical Association, &c. London: Hodder and Stoughton. 1935. Pp. 280. 5s.

2. The Doctor and the Public

By JAMES PETER WARBASSE, M.D. New York: Paul B. Hoeber, Inc. 1935. Pp. 572. $5.

1. HERE are two books dealing with the relationship between patient and doctor. Sir Henry Brackenbury begins by tracing the development of medicine through its three phases, the magical, the rational, and the scientific. He discusses the present outlook of medicine which, in addition to its previous two aspects, the curative and preventive, has now added to itself a third, namely, the constructive or perfective aspect. There follows a useful chapter on what the doctor and patient may reasonably expect of one another and the importance of mutual confidence and coöperation to defeat a common enemy is emphasised. The relation between the State and the doctor is next considered. In this chapter the organisation of the medical profession, the essentials of a medical service, and the present systems of State medical provision are described and evaluated. The author regards as inevitable the increasing intrusion of the State into medicine. "The greater concern of the community not only with its own collective health, but also with the personal health of all the individuals who compose it, is not a matter to grumble about but to welcome." The general practitioner must take his share of the increasing (and, may we add, often uninteresting ?) work of preventive medicine. A chapter is devoted to the work of the various kinds of hospitals, their medical staffing, and their relation with the profession outside. Some simple and admirable measures for increasing the comfort of hospital in-patients are suggested. There is a chapter on trained helpers and unscientific healers. Sir Henry Brackenbury has nothing very new to say about the latter, but perhaps does not allow duly for the chief reason that they exist at all, which must be not so much a primitive human craving for magic and mysticism as the all too frequent lack of therapeutic satisfaction obtainable even now from orthodox medicine. If our therapeutics were more effective, surely the raison d'être of the unscientific healer would disappear. The last two chapters deal with the training of a doctor and the future of medicine. No fault can be found with the type of doctor the author wishes to produce. The worst that could be said of the young man who possesses "previous equipment, assiduity and character," would be that he might prove to be a dull dog. Might not a certain liveliness and even humour be added with advantage to counterbalance his more solid qualities ? Visualising the medicine of the future as a social service, the author pictures the general practitioner as one of a team, preferably its captain, ministering to the requirements of the patient, who is not only a biological organism but also a human personality and a unit in a social system.

This book is everywhere interesting and clearly written. On controversial matters the author has been at pains throughout to put the whole case with scrupulous fairness before giving his own views.

2. Dr. Warbasse's approach to the subject is rather different. He is primarily concerned with the historical development of modern medicine and the status of the physician. Starting from the origin of medicine as manifested in animal behaviour, he traces its course through the age of magic to the age of science which began in Ancient Greece. He describes how medical science was kept alive by a few thinkers in the Middle Ages, and the steady advances it made during the sixteenth and seventeenth centuries. Medical progress in the eighteenth century was hindered by the growth of fads and cults, but, in the nineteenth, a scientific age developed a medical culture. Turning to the present, Dr. Warbasse has something to say on the difficulties of maintaining a high code of medical ethic in a competitive world. In his view the doctor must be rendered financially secure if he is to give his best service to the community. Pleading for more doctors, Dr. Warbasse raises once again the vexed question of the periodic medical overhaul by means of which earlier diagnosis of serious disease is to be attained with better prospect of ultimate arrest or cure. Against this might be argued the risk of increasing anxiety neuroses in a world already too full of fear of disease. As every practitioner knows, much professional time is already spent in trying to reassure cancerophobic patients, and one is tempted to wonder whether the sufferer from an incurable disease such as chronic nephritis might not be happier if it were not discovered at an early stage. Dr. Warbasse's book is written in the ingenuous, almost "popular," manner of many similar ones coming from the United States.

Manuel de sérologie pratique

By ÉDOUARD PEYRE. Paris: Librairie Félix Alcan. 1935. Pp. 271. Fr.20.

THIS little book gives an account of the usual serological methods employed in the laboratory. It includes not only immunological procedures, but also such chemical methods as the estimation of sugar, cholesterol, chlorides, calcium, &c., in the blood. A short account is given of the refractometer as a means of studying serum. On the other hand, it omits phosphatase determination, sedimentation-rate, and methods of examining the cerebro-spinal fluid. The descriptions of the methods are easy to follow, but they are not always those which would be used in this country.

THE LANCET

LONDON: SATURDAY, SEPTEMBER 28, 1935

PLASTER-OF-PARIS

"It were good that men in their innovations would follow the example of time itself," says Bacon, "which indeed innovateth greatly, but quietly and by degrees scarce to be perceived." Advance in most things human is however so gradual a process that change is upon us before we realise that it has taken place. Surgical advance is no exception. Mr. Pridie's articles on plaster technique, which appear in this and last week's issues of The Lancet, draw attention to one such development which has within the last five years altered the whole face of fracture treatment. It is hardly too much to say that plaster-of-Paris, in one form or another, has to-day superseded all other fixation splints, be they of wood or metal, and that the modern surgeon employs two types of apparatus only—plaster splints, and skeleton splints for use with weight traction. The methods which Mr. Pridie describes are the outcome of the experience of the orthopædic department of the Bristol Royal Infirmary, and have been standardised for that institution. They differ in detail only from those which are now in common use in every organised fracture clinic in the United Kingdom.

Plaster-of-Paris provides not only the cheapest but the most efficient method of external splinting. It requires neither a large stock nor an elaborate variety of apparatus, for by its employment all types of splint can be made, any number of the same kind can be duplicated, or new ones devised for every conceivable purpose. There is no storage problem, for splints are made when required, and thrown away when no longer needed. A well-made plaster splint is stronger, lighter, and more comfortable than one constructed of any other material. But its chief recommendation is its incomparable efficiency as a means for controlling the position of the limb which it encloses. For a plaster splint is an individual thing, fitting the part upon which it is moulded in every detail. Stock splints of wood or metal, however great their variety, can never be more than an approximate fit. Long bones are curved, splints are straight. Limbs vary infinitely in length, diameter, and contour, and in the relative proportions of their segments; splints can only be graded to a finite extent, and permit of a limited variation in the position of the joints adjacent to the injured segment. To make it fit and keep it comfortable a stock splint must be padded, and padding means the employment of a yielding structure which is incompatible with complete control. The well-designed plaster splint maintains position by its perfect adaptation to the limb, and not by pressure or traction. The reasons for the pre-eminent position of plaster-of-Paris to-day require no elaboration, but it is interesting to speculate why the method, which was old 4000 years before Christ, and which was apparently known to the surgeons of antiquity, should only have attained full recognition during the last five years. Why are fixed splints still made and sold; why are new ones devised from time to time; why is plaster-of-Paris still so little used outside the hospitals and fracture clinics? Many factors have undoubtedly contributed to this tardy recognition. Plaster-of-Paris, as is well known, must be blended with some fibrous material to be efficient as a splinting medium, much as concrete is reinforced with a core of metal strips. The older methods of plaster work made use of felt or house flannel for this purpose; accurate moulding was difficult and failures frequent. Perfection in method has come with the development of the plaster bandage, that protean unit that can be used in so many ways. But while good plaster work has been made very much easier by improvements in materials, it still remains an exacting art, demanding not only some experience and natural aptitude, but space, time, and skilled assistance. Lacking these last three, the busy worker is often obliged to use ready made splints in spite of their disadvantages. First-aid work and temporary immobilisation will always demand some readily applied apparatus.

The perfect plaster splint must retain the limb under all conditions in the desired position with complete comfort. It must be strong yet light, effective in use but easily removed when it is no longer required. It must therefore be planned upon engineering lines. The greater part of it is a retentive shell, which need only be thick enough to withstand chance blows, but it must be reinforced at its edges and buttressed where it is subjected to special stresses. Places that are too thin will weaken the whole; unnecessary thickness means unnecessary weight. Not only must it be well designed but it must be homogeneous, plaster and gauze being uniformly incorporated throughout, so that no trace is seen in section of its component layers. If part of the bandage is applied too dry, it will not set; if moistened too early, it will set prematurely and fracture on application. If one layer is set before the next is applied, or if successive layers are not well rubbed in, air spaces will appear and strength will be lost. The perfect plaster splint requires not only perfect technique but a perfect bandage. Every orthopædic surgeon is well aware that the making of such bandages is in itself an expert's job. The plaster-of-Paris must be of the finest quality, freshly prepared, and kept air-tight. The muslin must be fine enough to retain the powder, yet not so fine as to hinder the permeation of water. The powder must be rubbed in slowly by hand, not too much and not too little, and no lumps must be incorporated. The bandages must be rolled s loosely that they will take up water at on When made they must be stored in air-tight t and those tins must not be disturbed till the bandages are required, or the powder will shake out and accumulate in the bottom of the tins. The making of these bandages is a laborious, but highly skilled task, and it will often happen that, when a nurse who has been doing the work has been moved to a new post, the fracture work of a hospital may suffer for a whole month till her successor has acquired the necessary skill. One great advance, which has made uniformly good work possible to those who have the patience to learn the technique, is the introduction of the modern proprietary plaster bandage. Ready made bandages have always been obtainable, but these have till lately been inferior to the best of the hand-made ones, the chief fault being that the gauze upon which they were based has been too thick and rigid to permit that accurate moulding to the contour of the limb upon which success depends. The modern bandages have all the advantages of the hand-made article, with others of their own. Their quality is constant, and they keep indefinitely without deterioration. They absorb moisture more rapidly than hand-rolled bandages, and set firmly in less than ten minutes. When set they are stronger yet less brittle than ordinary plaster; the surface is hard polished and non-absorbent, the trimmed edges do not crumble, and casts made from them can be bisected, or cut open and sprung apart, without loss of strength. A splint made with this is thinner, lighter, and more durable than one of equal strength made from the best hand-rolled bandages. Perhaps the most striking advantage to the surgeon is the manner in which the plaster is incorporated with the bandage; this makes the construction of a splint a very much cleaner job, for no powder gets loose on the table and floor, and a more economical one, for small strips and bars can be cut out beforehand, moistened, and laid on at points of stress to reinforce the completed splint.

Plaster-of-Paris technique has culminated in the development of the unpadded plaster case, a method of fixation which we owe to Lorenz Böhler of Vienna. The unpadded case is the basis of modern fracture treatment; it is not merely an improved application of an old technique, but the expression of a physiological ideal. To the anatomical mind the aim of fracture treatment is the reconstruction of the bone in its former length, alignment, shape, and structure; to the physiological mind it is the restoration of the injured limb to its former function, taking into consideration not only the bone, but the joints, muscles, circulation, and innervation of the damaged segment—and the mentality of the patient. The ideals of form and function have been at variance throughout the ages; form has asked for splinting, fixation for movement. Many of us have seen the evil results of prolonged or excessive fixation, but only those older surgeons who are familiar with the results obtained by Lucas-Championnière and his disciples are aware of the ghastly failures for which the early movement school has been responsible. Movement of repair tissue leads to injury, injury calls forth hyperæmia, and hyperæmia in turn brings decalcification and deficient bone formation; on the other hand, complete rest leads to a decreased circulation, stiff muscles and joints, and the formation of avascular and sclerosed bone. It has remained for Böhler to point out the ideal, which is use of the injured part without movement of the injured structure. By such means the circulation is maintained at its normal level, neither deficient nor excessive, bone repair proceeds at its optimum rate, while the muscles and joints maintain their circulation and retain their movements. This ideal can only be reached by the use of a plaster case, accurately fitted to the surface of the limb and the contour of its bony points, which combines complete immobilisation with entire comfort. But the unpadded case is only successful if it is faultlessly applied; the chief danger is constriction of the limb, the commonest cause of failure the development of pressure sores due to wrinkles on its inner surface. Such sequelæ are usually due to some error, such as the attempt to alter the position of the limb after the case has been put on, and they will be avoided by careful study of Mr. Pridie's instructions.

The immensely improved results which are being obtained to-day in Colles's fracture and fractures of the tibia and fibula by this method of functional use of an immobilised segment are known widely enough to need no eulogy. Böhlerism has come to stay. Plaster-of-Paris reigns supreme.

THE PASSING OF OTORRHŒA

The frequency of discharging ears is not a bad index of the efficiency of medical care in any community. Some twenty years ago a mother brought one of her children to an out-patient department in a poor district of London complaining that, although the child was teething, there was no discharge from the ears, as had been the case with all her other children. Otorrhœa was in fact appallingly frequent before the medical inspection of school-children was instituted in London thirty years ago, and indeed until an efficient organisation for the treatment of these cases was gradually evolved some ten years later. But only a few of these cases attended hospital and then very irregularly; in the intervals the children were left to the care of their mothers, who were quite incapable of keeping the ears in a wholesome condition. Most of them were in consequence in a very offensive state, and the smell of an elementary class-room was often disgusting; no one who has not experienced it can imagine what it was like. And yet chronic discharge from the ears is preventable. If treated correctly from the beginning, the majority of cases of acute suppuration heal with intact drum and restoration of function; while most of those that persist can be cured by timely operation on the mastoid.

In London the campaign against otorrhœa began with the organised treatment in the schools under the control of the London County Council, the story of which is told in the school medical officer's report[1] for 1934. About 1909 district nurses were first employed to visit affected children in their homes. Although the ears were thus kept in a more hygienic condition, the method was not satisfactory; the cost per case was considerable, the nurse wasted much time in visiting a home often to find that the child was out, and the work was not under medical direction. Four years later "minor ailment departments" were introduced at school treatment centres, where the district nurses worked under medical supervision; these have been gradually increased in number until there are now 70 covering the whole of London; this led to a great improvement in the conditions, and got rid of the offensive ears altogether. The doctors in charge were not, however, specialists in otology, and the departments tended to be clogged by uncured cases. An "ear inspection clinic" was then arranged, to which were referred cases from the surrounding minor ailment departments. In-patient treatment was also secured for those whose cure could only be expected from mastoid operation or other in-patient treatment. This clinic proved to have great possibilities and the system was gradually extended to other areas; an aural surgeon of experience was appointed to each, and in 1920 zinc ionisation was added to the routine of treatment. At first cases from the minor ailment departments which did not clear up after three months' treatment were sent to the special clinics, but in 1925 it was arranged that all cases which had not recovered in one month should be so referred. This is a point of the utmost importance for it enables the children to receive expert attention at the most critical period of the disease. In the early years treatment by operation was greatly hampered by the long wait for hospital beds, but this difficulty was surmounted by the provision of adequate accommodation by the Metropolitan Asylum Board, and more lately at the L.C.C. special hospitals. Children on leaving hospital now receive after-care at a special centre.

Figures given in the report show the success of this work in reducing the frequency of otorrhœa; thus in the period since 1911, covering the twenty-five years of His Majesty's reign, the percentage of children suffering from discharging ears has fallen from 3·7 to 0·9. Nevertheless in the year 1934, 4200 discharging ears were observed, of which 2261, or 53·8 per cent., were cured; 1271 of these were old cases returning for observation, showing that relapses are still occurring. These figures relate to ears, not patients, the proportion of cases cured being 70 per cent. or more. Despite this enormous improvement much remains to be done; there is still far too much otorrhœa among the children of our county schools. The best prospect of further improvement probably lies in paying greater attention to acute otitis in its earliest stage. Since the child with earache is kept away from school, the chief hope of progress is to be found in enlisting the interest of the family doctor and in educating the public in the importance of early treatment.

FORCEPS HEAVY AND LIGHT

THAT obstetricians do not practise what they preach is the conclusion drawn by Mr. WRIGLEY from the study of the case records of "one of the leading maternity homes in London" (see p. 702), a study presumably undertaken in order to confirm or refute an impression gained from other less definite evidence. The patients in the nursing-home to whose records he had access were for the most part under the care of teachers of obstetrics. Mr. WRIGLEY has ascertained that delivery was completed by forceps in as many as 203 of the last 300 consecutive cases (primiparæ) admitted. On their face value these figures certainly support his thesis that it is likely to be more profitable to find some way of reducing the risks associated with the application of forceps than to attempt to stop their use. He contends that the powerful but dangerous instrument now in vogue was designed and constructed to enable the accoucheur to deal with a woman "whose pregnancy had had no supervision and in whom obstructed labour had occurred, the fœtal head having failed to descend in the pelvis." And we agree with him that to-day such disproportion would stand a far better chance of being discovered either during pregnancy or early in labour, when Cæsarean section rather than forcible delivery would be performed. Nowadays delay in labour, when it occurs with the head at the pelvic brim or in the mid-pelvis, results generally, as Mr. WRIGLEY says, from incomplete rotation or flexion or a posterior occiput; in such cases the proper course is anæsthetisation of the patient, and a thorough examination to ascertain the cause of the delay, possibly followed by Cæsarean section, rather than hasty application of forceps long enough to reach and grasp the fœtal head and strong enough to haul it out. Reiteration of the potential dangers of such an instrument is, in Mr. WRIGLEY's view, futile so long as the medical student sees it in the hands of house officers for routine forceps delivery of fœtal heads low in the pelvis. His solution is the substitution of a short light forceps for the axis-traction model, being convinced from personal experience, detailed below, that it will meet most of the needs of the doctor and will enable him to shorten labour without risk to mother or child.

In the last 58 consecutive deliveries of primiparæ in his own practice the fœtus presented the vertex. In 23 of them delivery was unaided; in 32 the head was lifted through the pelvic floor with a short forceps weighing less than 10 oz. In 2 of 3 cases where manual rotation of a persistent occipito-posterior position was required the fœtus was delivered easily with the light forceps. In the third the fœtal head did not sink into the pelvic cavity after rotation and the long forceps was applied. Mr. WRIGLEY admits that the 32 women would eventually have delivered them selves; his principle in expediting labour is tl humane one that it is the duty of the attenda to alleviate pain in so far as this is possible witl
